Advice on Sustainable Management of Coastal Shingle Resources

Kenneth Pye
Simon J. Blott

Kenneth Pye Associates Ltd.

Report No 273

About Natural Resources Wales

Natural Resources Wales' purpose is to pursue sustainable management of natural resources. This means looking after air, land, water, wildlife, plants and soil to improve Wales' well-being, and provide a better future for everyone.

Evidence at Natural Resources Wales

Natural Resources Wales is an evidence based organisation. We seek to ensure that our strategy, decisions, operations and advice to Welsh Government and others are underpinned by sound and quality-assured evidence. We recognise that it is critically important to have a good understanding of our changing environment.

We will realise this vision by:

- Maintaining and developing the technical specialist skills of our staff;
- Securing our data and information;
- Having a well-resourced proactive programme of evidence work;
- Continuing to review and add to our evidence to ensure it is fit for the challenges facing us; and
- Communicating our evidence in an open and transparent way.

This Evidence Report series serves as a record of work carried out or commissioned by Natural Resources Wales. It also helps us to share and promote use of our evidence by others and develop future collaborations. However, the views and recommendations presented in this report are not necessarily those of NRW and should, therefore, not be attributed to NRW.

Report series: NRW Evidence Report
Report number: 273
Publication date: August 2018

Contents

1.	Crynodeb Gweithredol	11
2.	Executive Summary	13
3.	Background: scope and purpose	15
3.1.	The nature of shingle and the need for further guidance	15
3.2.	Work undertaken.....	16
3.3.	Report structure	19
4.	The sedimentary properties of shingle	20
4.1.	Particle size	20
4.2.	Particle shape	24
4.3.	Sources and lithological composition of shingle	25
5.	Shingle processes and landforms	30
5.1.	Movement of shingle by waves and currents.....	30
5.2.	Swash and drift aligned beaches	30
5.3.	Types of coastal shingle accumulation	31
5.3.1.	Cross-shore distribution of shingle	31
5.3.2.	Shingle features classified on the basis of plan form	33
5.3.2.1.	Pocket beaches	34
5.3.2.2.	Fringing beaches	35
5.3.2.3.	Barrier beaches	38
5.3.2.4.	Beach ridge plains	43
5.3.2.5.	Fan delta.....	44
5.3.2.6.	Forelands.....	45
5.3.2.7.	Classification based on sedimentary architecture and morphological evolution	46
5.4.	Response of shingle barriers to rising sea level.....	47
6.	Shingle vegetation and other conservation interests	50
6.1.	Requirements for establishment of shingle vegetation	50
6.2.	Important vegetated shingle sites in Wales	53
6.3.	Other ecological conservation interests	56
6.4.	Geomorphological conservation interests.....	56
7.	Flood and Coastal Erosion Risk Management Significance	59
7.1.	Factors affecting FCERM significance.....	59
7.2.	Potential benefits and problems associated with shingle	60
7.3.	FCERM significance of shingle in Wales	62
7.4.	FCERM-related shingle management issues in Wales	64
7.5.	FCERM and SMP Policy.....	66
8.	Shingle beach management methods.....	67
8.1.	Methods used to manage coastal flooding and erosion risk.....	67
8.1.1.	Beach re-profiling.....	67
8.1.2.	Shingle recycling.....	70
8.1.3.	Shingle by-passing	71

8.1.4.	Beach replenishment.....	71
8.1.5.	Structures to control alongshore sediment movement.....	73
8.1.5.1.	Groynes.....	73
8.1.5.2.	Rock armour revetment.....	76
8.1.5.3.	Timber revetment.....	77
8.1.5.4.	Asphalt aprons.....	78
8.1.5.5.	Offshore breakwaters and reefs.....	78
8.1.5.6.	Concrete walls and promenades.....	80
8.2.	Methods for the control of shingle impact on land drainage.....	81
9.	Case Studies.....	85
9.1.	Case Study 1: Dinas Dinlle and Morfa Dinlle.....	85
9.1.1.	'Knock-on' down-drift effects of hard shore defences.....	85
9.1.2.	Likely effects of accelerated sea level rise.....	90
9.1.3.	A suggested 'good practice' way forward.....	90
9.2.	Case Study 2: Newgale, Pembrokeshire.....	90
9.2.1.	Barrier rollover and shingle 'squeeze'.....	90
9.2.2.	Good practice assessment of management options.....	96
9.3.	Case Study 3: Aber Dysynni, Gwynedd.....	97
9.3.1	Effect of alongshore drift on the flushing efficiency of the Dysynni estuary.....	97
9.3.2.	Channel maintenance by dredging and shingle bypassing.....	100
9.3.3.	Future management options.....	102
9.4.	Case Study 4: Pontllyfyni to Dinas Dinlle, Gwynedd.....	103
9.4.1	Combined problems of land drainage, barrier rollover and alongshore drift.....	103
9.4.2.	Likely effects of future sea level rise.....	103
9.4.3.	Options for future management.....	104
10.	Conclusions and recommendations relating to shingle management best practice.....	110
10.1.	Artificial shingle banks and replacement with more 'natural' profiles.....	110
10.2.	Provision of secondary flood defences and resilience measures.....	112
10.3.	Hard defences vs coastal adaptation.....	112
10.4.	Incorporation of beach creation and maintenance into scheme design.....	112
10.5.	Best practice associated with shingle beach management schemes.....	114
11.	References.....	117
12.	Appendices.....	126
	Appendix A: Shingle beaches identified in this study.....	126
	Data Archive Appendix.....	167

List of Figures

Figure 1 Distribution of the shingle sites identified in this study	18
Figure 2 Particle size class terminology proposed by Blott & Pye (2012), based on a modification of Wentworth's (1922) grade scale, compared with that used BS:1377-2 1990 (BSI 1990) and ISO:14688-1 2002 (ISO 2002)	21
Figure 3 Example particle size frequency histograms for samples of (a) clean upper beach shingle sediment from Glanllynau), and (b) bimodal mixed sand-shingle sediment from Afon Wen, Gwynedd.....	22
Figure 4 Example of a particle size ternary diagram, defined by the percentages of shingle (gravel and small boulders , 2 – 256 mm), sand (0.063 to 2 mm) and mud (<0.063 mm) in 256 beach samples collected by Gwynedd Council Coast Protection Department from beaches between Aberdovey and Morfa Dinlle in 2010-2011	23
Figure 5 Schematic diagram showing patterns of variation in particle size potentially found on shingle beaches: (1) vertically; (2) cross-shore; and (3) along-shore.	24
Figure 6 Compositionally heterogeneous mixture of cobbles and pebbles sourced primarily from glacial till cliffs, Hen Borth, Anglesey	26
Figure 7 Upper beach formed of sub-angular cobbles and pebbles derived mainly by wave reworking of local glacial moraine deposits exposed in the intertidal zone, north end of Whiteford Sands, Gower	26
Figure 8 Rounded clasts of hard Silurian greywacke and vein quartz at Borth, Ceredigion, derived mainly from the cliffs around Aberystwyth. Note also the rounded clast of concrete in the right-centre of the photograph	27
Figure 9 A barrier beach / barrier spit complex formed substantially of limestone quarry waste, Pwlldu Bay, Gower	28
Figure 10 Fringing shingle upper beach composed of reworked slag, brick and concrete, east of Burry Port	28
Figure 11 Angular rock (mainly limestone with some sandstone) placed for FCERM purposes at Llanfairfechan, North Wales	29
Figure 12 Mid-foreshore lag deposit composed of infrequently moved small boulders and shingle, Kenfig, South Wales.....	32
Figure 13 Upper beach and storm beach ridge composed of shingle at Pensarn, North Wales (photograph taken close to time of high tide)	33
Figure 14 Schematic representation of the main morphological types of coastal shingle accumulation	34
Figure 15 Aerial photograph of Nolton Haven, Pembrokeshire. An example of a pocket beach with shingle upper beach and wide sandy lower beach.....	35
Figure 16 Fringing shingle upper beach in front of sand dunes at Aberdovey	36
Figure 17 Fringing shingle beach in front of eroding soft cliffs, north of Aberaeron, Cardigan Bay.....	34
Figure 18 Example of a narrow fringing shingle upper beach, Amroth, Carmarthenshire....	35
Figure 19 Example of a relatively wide fringing shingle and boulder beach in front of concrete sea defences and Aberthaw Power Station, both partially built on top of shingle ...	37
Figure 20 Aerial photograph (a) and Composite LiDAR DTM (b) of the Criccieth – Craig Ddu shingle barrier beach with Cambrian Coast railway line immediately behind. The Afon Cedron once reached the sea towards the western end of the barrier but now discharges through an artificial cut at the eastern (up-drift) end. Excavated shingle forms two vegetated NW – SE oriented mounds on the west side of the cut. The shingle ridge is subject to localised wash-	

over during storms and any transgressive shingle reaching the Cambrian Coast railway line is removed reactively.....38

Figure 21 Aerial photograph (a) and LiDAR DTM (b) of the Carreg y Defaid – Carreg yr Imbill barrier in northern Tremadoc Bay. At its western end the barrier is low and consists of relatively coarse shingle ridge which has been reinforced with rock armour; at the eastern end near the former island of Carreg yr Imbill, the barrier is much wider and consists of dunes overlying mixed shingle and sand. The section of barrier between South Beach and Carreg yr Imbill could arguably be classified as a tombolo, while the section between Carreg yr Imbill and the entrance to Pwllheli harbour has the form of a spit. Aerial photography flown 2013-14, composite LiDAR DTM flown 2013-1539

Figure 22 The Afon Dwyfor barrier spit, Tremadoc Bay. Note the very narrow nature of the spit at its neck. (a) Aerial photography flown 2013-14; (b) LiDAR DTM flown 201440

Figure 23 The Tanybwloch barrier spit at the mouth of the River Ystwyth. Note that the river has cut into the back side of the ridge as it has moved landwards, requiring placement of rock armour on the outside meander bend. The Tanybwloch barrier now receives very little new shingle from the cliffs and fringing beaches to the south and the southern end of the barrier has narrowed considerably in recent decades, despite rock armour protection. Long-term maintenance of the barrier in its present form was judged by Pethick et al. (2003) to be unsustainable. (a) Aerial photography flown 2013; (b) LiDAR digital terrain model, flown 6th to 13th January 2012.....41

Figure 24 Ro-Wen (Fairbourne) Spit (buildings removed). At the extreme southern end near the Friog cliffs the barrier is very narrow and composed of coarse shingle and cobbles; much of the rest of the west-facing part of the barrier has a uniform width and consists of smaller shingle and cobbles, while the northwest-facing northern section is composed of finer shingle and sand capped by dunes. Much of the ridge is backed by concrete defences which provide additional coastal flood protection for the village, Fairbourne light railway and access road to the Barmouth ferry. Concerns about diminution of the shingle / cobble upper beach at Friog have led to proposals to import 4000 tonnes of cobble from an inland quarry source. (a) Aerial photography flown 2013; LiDAR DTM flown 200942

Figure 25 Esgair Cemlyn, Anglesey: an example of a relatively narrow shingle barrier which originated as a spit with a shallow tidal lagoon and intertidal flats behind, but which is now attached to an artificial mound and weir which regulates water levels in the lagoon.....41

Figure 26 The heavily man-modified coast between Llanddulas and Kinmel Bay, North Wales, including the progradational embayment-fill shingle beach ridge plain between Llanddulas and Pensarn. (a) Aerial photography flown 2013-14; (b) Composite LiDAR DTM, flown 2007-2014.....44

Figure 27 Fringing, barrier beach, barrier spit and alluvial fan delta types of shingle accumulation on the heavily man-modified coast between Afon Ogwen and Llanfairfechan. Composite LiDAR DEM, flown 2007-2014.....45

Figure 28 A composite sand and shingle foreland at Morfa Conwy.....45

Figure 29 Three types of shingle ridge structures which display differing stratigraphic architecture in response to contrasting histories of morphological development.....47

Figure 30 Schematic diagram showing the evolution of swash-aligned shingle barriers in response to sea level rise and dependence on sediment supply49

Figure 31 Schematic diagrams of barrier rollover in closed and semi-open sediment compartments50

Figure 32 Example of pioneer vegetation development close to the MHWS line on a fringing shingle beach with low wave exposure, Menai Strait east side52

Figure 33 Example of a slowly retreating vegetated shingle ridge, Pensarn, North Wales ...53

Figure 34 Sites in Wales identified by Sneddon & Randall (1993b) in terms of importance for vegetated shingle. Site numbers and names are those used in the present study	54
Figure 35 Shingle features within Sites of Special Scientific Interest and where the designation citation states that the shingle or vegetated shingle is a 'special' feature.....	55
Figure 36 Important shingle structures in Wales identified by Stapleton (1996). Site numbers and names are those used in the present study	57
Figure 37 Schematic diagram illustrating different levels of FCERM significance of shingle features	59
Figure 38 Narrow shingle ridge fronting single storey housing, Aberaeron	60
Figure 39 High value assets inland of the shingle beach at Pensarn, North Wales coast: from left to right are the A55 trunk road, the Chester to Holyhead railway line and a caravan park access road.....	60
Figure 40 Natural impact on FCERM significance/effectiveness of shingle beaches and structures	65
Figure 41 Section of the Cambrian Coast railway between Barmouth and Llanaber which is protected only by a shingle fringing beach. In the 2013-14 stormy winter transgression of shingle onto the line occurred, and further north parts of the line were washed away.....	68
Figure 42 The eastern part of Caswell Bay, Gower. During the 2013-14 winter storms, wave-tossed shingle caused significant damage to the beach front café,; a significant proportion of the remaining shingle was removed from the toe of the promenade by the local authority and placed on the upper beach in a different part of the Bay where it was unlikely to cause further damage (photograph by J. Rewbridge, City and County of Swansea Council)	69
Figure 43 Maintained shingle ridge at Llanrhystud, south of Aberystwyth, looking north... .	68

1. Crynodeb Gweithredol

Mae 'graean bras' (shingle) yn derm anffurfiol am waddodion sy'n cynnwys gronynnau gan fwyf y cyfeirir atynt yn gyffredinol fel 'cerigos' a 'chobls', ond a allai hefyd gynnwys swm arwyddocaol o dywod a chlogfeini. Yng Nghymru, mae graean bras yn bwysig am sawl rheswm, yn cynnwys rheoli risg llifogydd ac erydu arfordirol (FCERM), cadwraeth geomorffolegol a daearegol, cadwraeth natur a hamdden. Mae graean bras llystyfiant o bwysigrwydd cadwraeth Ewropeaidd, dan risg o gyfuniad o ddatblygiad i ffin arfordirol, rheolaeth dwys o draethau a chynnydd yn lefel y môr ("gwasgfa arfordirol"). Mae graean bras llystyfiant yn fregus, ac yn hawdd i'w ddifrodi gyda symudiad cerbydau, pobl a'r gwaddod ei hun. Er bod yna hanes hir o ymyraethau FCERM ar draethau graean bras yn y Deyrnas Unedig, mae'r canllaw yn ymwneud â rheolaeth arfer gorau yn gyfyngedig iawn. Mae CNC wedi nodi angen i ddatblygu canllawiau gwell parthed gwaith ymyrraeth FCERM er mwyn diogelu buddiannau ehangach nodweddion graean bras yng Nghymru. Mae'r adroddiad hwn wedi ei baratoi i hysbysu datblygiad y canllaw hwn.

Mae tair tasg wedi eu cyflawni yn rhan o'r prosiect: (1) adolygiad o lenyddiaeth, tystiolaeth, canllawiau a gwybodaeth bresennol i sefydlu gwerth a rôl nodweddion graean bras a chynefinoedd wrth gyflawni FCERM yng Nghymru, yr ymyraethau FCERM a allai fod yn berthnasol i draethau graean bras, strwythurau a chynefinoedd, a'r risg o effeithiau negyddol ar nodweddion graean bras a chynefinoedd o ganlyniad i ymyraethau FCERM; (2) dethol pedwar astudiaeth achos mewn gwahanol leoliadau amgylcheddol ble mae ymyraethau FCERM wedi eu gweithredu; mae'r lleoliadau a ddewiswyd (Dinas Dinlle, Niwngwl, Aber Dysynni a Pontllyfni) yn arddangos gwahanol broblemau, gwahanol ymatebion rheoli hanesyddol, a gwahanol ddewisiadau ar gyfer y dyfodol; (3) nodi dulliau arfer gorau a fydd yn sicrhau rheolaeth gynaliadwy o gynefinoedd graean bras yng Nghymru yn y tymor canolig i hir, a'r gofynion ar gyfer casglu data arolwg gwaelodlin a monitro dilynol.

Yn rhan o'r astudiaeth bresennol, mae 403 o safleoedd graean bras wedi eu nodi ar arfordir Cymru, yn seiliedig ar asesiad o'r ffotograffiaeth o'r awyr mwyaf diweddar sydd ar gael, data LIDAR ac arolygon ar droed o'r tir. Rhestrir y safleoedd hyn a'u priodweddau yn Atodiad 1. Mae prif gorff yr adroddiad yn ystyried agweddau allweddol o raean bras y mae angen eu deall wrth ddatblygu strategaeth mesur graean bras FCERM priodol, yn cynnwys priodweddau gwaddodol, natur prosesau graean bras, tiffurfiau a llystyfiant, arwyddocâd FCERM graean bras, a dulliau rheoli sydd ar gael. Fe ystyrir pedwar enghraifft o astudiaethau achos, gan wneud argymhellion parthed rheolaeth arfer gorau graean bras.

Yn rhan o arfer gorau, dylid datblygu cynllun rheoli traeth (BMP) graean bras sy'n ceisio lleihau'r straen ar, a chynnydd gwytnwch cynefinoedd graean bras, atal colledion, difrod neu ddarniad cynefinoedd a rhywogaethau, a cheisio sicrhau gwerth a buddion yr amrywiaeth o wasanaethau ecosystem a ddarperir. Dylid cadw amhariad ar yr arwyneb i isafswm er mwyn galluogi i llystyfiant graean bras ddatblygu; mae ailbroffilio anaml o rannau uwch

traethau a chefnennau traethau yn annog sefydlogrwydd a chroniad gwaddod mân gwagleol sy'n ofynnol ar gyfer datblygiad llystyfiant graean bras.

Yn rhan o BMP, dylid monitro lefelau traethau yn rheolaidd i ragweld problemau a gofynion ymyrraeth cyn iddynt ddod yn broblemau mawr sydd angen gwaith argyfwng. Dylid cyflawni astudiaeth arolwg gwaelodlin geomorffolegol i hysbysu datblygiad y BMP ac unrhyw gynlluniau posibl, gydag asesiadau ailadrodd ar ysbeidiau o 5 mlynedd wedi eu hysbysu gan arolygiadau safle blynyddol a dadansoddiad o ddata monitro amgylcheddol. Dylai'r astudiaeth arolwg gwaelodlin geomorffolegol gynnwys adolygiad o lenyddiaeth gefndirol, archwiliad o fapiau hanesyddol, siartiau, ffotograffiaeth o'r awyr data LIDAR, arolwg topograffeg i'r ddaear a data arolwg gwaddod, asesiad o ddata prosesau arfordirol ac arolwg ar droed o'r safle. Os nad oes data arolwg tir neu o'r awyr diweddar ar gael, dylid comisiynu arolygon newydd i hysbysu'r asesiad, a chyn cyflawni unrhyw waith ymyrraeth FCERM. Yn ogystal, dylid cyflawni arolwg gwaelodlin gan ailadrodd monitro ar ysbeidiau yn ddibynnol ar bwysigrwydd a sensitifrwydd cadwraeth y safle.

2. Executive Summary

'Shingle' is an informal term for sediments which consist predominantly of particles which are commonly referred to as 'pebbles' and 'cobbles', but which may also contain significant amounts of sand and boulders. Coastal shingle in Wales is important from several standpoints, including flood and coastal erosion risk management (FCERM), geomorphological and geological conservation, nature conservation, and recreation. Vegetated shingle is of European conservation importance, at risk from a combination of development of the coastal margin, intensive beach management and sea level rise ("coastal squeeze"). Shingle vegetation is fragile, and easily damaged by the movements of vehicles, people, and the sediment itself. Although there is a long history of FCERM interventions on shingle beaches in the UK, there is only limited guidance relating to best practice management. NRW have identified a need to develop better guidance relating to FCERM intervention works in order to protect the wider interests of shingle features in Wales. This report has been prepared to inform the development of this guidance.

Three tasks have been undertaken as part of the project: (1) a review of existing literature, evidence, guidance and information to establish the value and role of shingle features and habitats in delivering FCERM in Wales, the FCERM interventions potentially applicable to shingle beaches, structures and habitats, and the risk of negative impacts on shingle features and habitats as a result of FCERM interventions; (2) selection of four case studies in different environmental settings where FCERM interventions are applied; the locations chosen (Dinas Dinlle, Newgale, Aber Dysinni and Pontllyfini) illustrate different issues, different historical management responses, and differing future options; (3) identification of best practice approaches which will secure the sustainable management of shingle habitats in Wales over the medium to long term, and the requirements for baseline data collection and subsequent monitoring.

As part of the present study 403 shingle sites have been identified on the Welsh coast, based on an assessment of the most recent available aerial photography, LIDAR data and ground walkover surveys. These sites and their attributes are listed in Appendix 1. The main body of the report considers the key aspects of shingle which need to be understood in developing an appropriate FCERM shingle management strategy, including sedimentary properties, the nature of shingle processes, landforms, and vegetation, the FCERM significance of shingle, and available management methods. Four case study examples are considered, and recommendations made relating to best practice shingle management.

As part of best practice, a shingle beach management plan (BMP) should be developed which seeks to reduce the stress on, and increase the resilience of, shingle habitats, prevent loss, damage or fragmentation of habitats and species, and seek to secure the value and benefits of the range of ecosystem services provided. Surface disturbance should be kept to a minimum in order to allow shingle vegetation to develop; infrequent re-profiling of the upper parts of

beaches and beach ridges encourages stability and the build-up of interstitial fine sediment required for shingle vegetation development.

As part of the BMP regular monitoring of beach levels should be undertaken to anticipate problems and intervention requirements before they become major issues which require emergency works. An adequate geomorphological baseline study should be undertaken to inform the development of the BMP and any potential schemes, with repeat assessments at intervals of 5 years informed by annual site inspections and analysis of environmental monitoring data. The geomorphological baseline study should include a review of background literature, examination of historical maps, charts, aerial photography, LIDAR data, ground topographic survey and sediment survey data, assessment of coastal processes data, and a site walkover survey. If no recent ground or aerial survey data are available, new surveys should be commissioned to inform the assessment, and prior to any FCERM intervention works being undertaken. In addition, an ecological baseline survey should be undertaken with repeat monitoring at intervals depending on the conservation importance and sensitivity of the site.

3. Background: scope and purpose

3.1. The nature of shingle and the need for further guidance

'Shingle' is an informal term for sediments which consist predominantly of particles (or 'clasts') which are commonly referred to as 'pebbles' and 'cobbles', but which may also contain significant amounts of sand and boulders. Coastal shingle beaches and beach ridges in Wales are important from several standpoints, including flood and coastal erosion risk management (FCERM), geomorphological and geological conservation, nature conservation, and recreation. In the past, shingle was also extensively exploited as a resource for construction purposes, although this is no longer the case. Shingle can form a variety of geomorphological features, including intertidal bars, spits, storm beach ridges, beach ridge plains and forelands. These features provide habitats which often support specialist flora and fauna and which are of very restricted extent in Wales, and within Europe more generally. A large proportion of the shingle resource which originally existed on the Welsh coast has been destroyed or damaged by gravel extraction, coastal defence works and urban development, and hence there is a need to ensure that what remains is managed in a way which can maintain, and where possible enhance, the geomorphological and nature conservation interests. FCERM interventions such as beach re-profiling, re-cycling, channel clearance and construction of hard defences can potentially have damaging impacts on shingle features and habitats by destroying natural forms, interfering with natural processes and disturbing shingle surfaces to the detriment of vegetation and fauna. Over time, these changes may lead to habitat fragmentation or loss, and impact directly on species.

Vegetated shingle is recognized as being of European conservation importance, at risk from a combination of development of the coastal margin, intensive beach management and sea level rise ("coastal squeeze"). Sneddon & Randall (1993b) estimated the total area of vegetated shingle in Wales to be less than 100 ha. Vegetated shingle is also a rare habitat in Europe as a whole (Doody 2001a,b). Two shingle vegetation communities, *Annual vegetation of drift lines* and *Perennial vegetation of stony banks*, are designated under Annex 1 of the European Habitats Directive, and Coastal Vegetated Shingle is a UK Biodiversity Action Plan (BAP) priority habitat (Maddock, 2008).

Shingle vegetation is fragile, and easily damaged by the movements of vehicles, people, and the sediment itself. Projected increases in the rate of sea level rise, and potentially the frequency and magnitude of storms, suggest that the pressures on shingle beaches and beach ridges are likely to increase in the near future as a result of direct erosion and, in many areas, more intense beach management and/or hard coastal engineering interventions.

Although there is a long history of FCERM interventions on shingle beaches in England and Wales, there is only limited guidance relating to best practice management. Some guidance on shingle beach management for FCERM purposes was provided in the first edition of the Beach Management Manual (Simm et al., 1996), but this gave little attention to geomorphological and

nature conservation aspects. A scoping study to determine guidance needs for barrier beaches (including sand, shingle and mixed sand - shingle beaches) was undertaken by Stripling et al. (2008) on behalf of the Environment Agency (EA). These authors noted (p. iii) that “at present there is scant guidance available which enables a balance between intervention and natural heritage interests to be achieved, and coastal managers are sometimes left to struggle through on a trial and error basis when seeking solutions”, and that “part of the reason for the lack of management guidelines for barrier beaches is our relatively poor understanding of the processes driving their short-term morphology and long-term evolution”. The report reviewed the literature relating to barrier beach processes and morphological change, methods of predicting barrier overtopping, and management methods, and recommended further research to underpin a Best Practice Guide. A catalogue of barrier beaches in England and Wales was made available through a website, which is no longer maintained. No major national follow-up study was commissioned following this report, although a number of more locally-focused projects were undertaken by individual EA regions (e.g. Dornbusch & Cargo, 2011), and advice on a broader approach to shingle beach management was included in the second edition of the Beach Management Manual (Rogers et al., 2010).

The damaging UK winter storms of 2013-14 and 2015-16 brought the issue of shingle and mixed sand-shingle beach management back into sharp focus, particularly in southwest England and Wales. Emergency works, including shingle beach / ridge re-profiling and importation of shingle or rock from alongshore or external sources were necessary at many locations on the Welsh coast. Following these events, NRW identified a need to develop better guidance relating to FCERM intervention works in order to protect the wider interests of shingle features in Wales. This report has been prepared to inform the development of this guidance.

3.2. Work undertaken

Three tasks have been undertaken as part of the study:

- (1) a review of existing literature, evidence, guidance and information to establish:
 - the value and role of shingle features and habitats in delivering FCERM in Wales
 - the FCERM interventions potentially applicable to shingle beaches, structures and habitats
 - the risk of negative impacts on shingle features and habitats as a result of FCERM interventions
- (2) selection of four case studies in different environmental settings where FCERM interventions are applied; the locations chosen illustrate different issues, different historical management responses, and differing future options:

- Dinas Dinlle and Morfa Dinlle – the impact of hard engineering structures on shingle transport and maintained shingle bank flood defences down-drift
 - Newgale – the challenges posed by shingle ridge roll-back towards significant coastal infrastructure, requiring consideration of asset relocation and habitat creation through coastal adaptation
 - Aber Dysynni – the effect of alongshore drift of shingle on maintenance of land drainage and tidal exchange in a significant estuary (the Dysynni), historically controlled by construction of a terminal groyne, training walls and more recently by dredging and sediment by-passing
 - Pontllyfni to Dinas Dinlle – where a combination of alongshore drift and barrier rollover presents long term challenges for the maintenance of land drainage and traditional agricultural practices in the coastal plain, but also offers opportunities for the re-creation of dynamic coastal landforms and a range of coastal habitats.
- (3) identification of best practice approaches which will secure the sustainable management of shingle habitats in Wales over the medium to long term, taking account of sustainable management of natural resources principles, the steps necessary to determine the most sustainable FCERM approach in any given area, requirements for baseline data collection and subsequent monitoring and data assessment.

As part of the present study a new assessment of shingle features on the Welsh coast, including their FCERM significance, has been undertaken using 2009-2017 aerial photography, 1: 10 000 and 1: 25 000 Scale Ordnance Survey maps, British Geological Survey 1: 50 000 scale geological maps, LiDAR survey data relating to the period 2003 – 2017, discussions with selected coastal managers and site visits to selected locations. An expanded list of shingle localities in Wales has been developed which includes a total of 403 sites whose distribution is shown in Figure 1. A list of the largest twenty sites in terms of extent of bare and/or vegetated shingle is presented in Table 1. The largest areas of shingle are found at East Aberthaw, Borth and Aber Dysynni. In terms of area none of the Welsh sites approach the major shingle formations found in England such as Dungeness (1742ha), Orfordness (412ha), Chesil Beach (321ha) and Rye (234 ha), based on areal extents for the English sites reported by Murdoch et al. (2009). Nevertheless, as discussed later in this report, a number of Welsh sites are important in terms of the combination of functions which they serve.

Figure 1 Distribution of the shingle sites identified in this study

Table 1 The twenty largest accumulations of Welsh coastal shingle by area

Site Number	Site	SMP2 Policy Development Zone	Morphological Type of shingle accumulation	Bare shingle area (ha)	Vegetated shingle area (ha)
13	Pebble Beach, Barry	The Knap to Watch House Beach	Barrier	8.63	0.18
14	Porthkerry	The Knap to Watch House Beach	Barrier	6.79	0.46
16	Watch House Beach, East Aberthaw	The Knap to Watch House Beach	Barrier Beach / Spit	38.25	0.73
42	Pwlldu Bay	Mumbles Head to Worms Head	Barrier Beach	3.16	0.94
44	Pennard Burrows	Mumbles Head to Worms Head	Barrier Beach	0.58	0.22
68	Amroth Beach	Dolwen Point to Giltar Point	Fringing	3.28	0.02
119	Pickleridge Beach	Little Castle Head - St Anns Head	Barrier Beach Spit	1.98	4.70
157	Newgale Sands:Sibbernock-Newgale	St Bride's Bay	Barrier Beach	4.16	0.03
184	Aber Mawr	St David's to Strumble Head	Barrier Beach	1.03	0.00
220	Pen yr Ergyd	The Teifi	Barrier Spit	0.84	0.25
233	Aberaeron to Aberarth	Aberaeron Plateau	Fringing	4.09	0.00
246	Traeth Tanybwlich, Aberystwyth	Aberystwyth	Barrier Beach/Spit	7.07	3.44
253	Borth	Dyfi	Barrier Spit	14.94	20.33
256	Tywyn to Aber Dysynni	Dyfi	Barrier Spit	8.30	24.06
262	Barmouth to Llanaber	Barmouth and the Mawddach	Fringing	2.63	0.00
269	Graig Ddu to Criccieth	Coastal Snowdonia	Barrier Beach	7.26	3.43
271	Afon Dwyfor	Coastal Snowdonia	Barrier Spit	9.05	12.37
275	Pen-ychain to Pwllheli	The South Llyn Bays	Barrier Beach	6.73	5.87
280	Porth Neigwl	Trwyn Cilan to Carreg Ddu	Fringing	10.19	0.00
297	Aberdesach	north Llyn	Barrier Beach/Spit	1.16	0.42
301	Pontllyfni to Ynys	Menai Strait	Barrier Beach/Spit	4.41	4.66
304	Morfa Dinlle	Menai Strait	Barrier Spit	14.61	11.89
346	Cemlyn Bay, Anglesey	north Anglesey	Barrier Beach	3.78	1.86
355	Dulas Bay, Anglesey	East Bays	Barrier Spit	0.35	0.02
368	Porthllongdy Spit	East Bays	Spit	0.70	0.16
396	Pensarn	Little Orme to Clwyd Estuary	Beach Ridge Plain	12.7	6.73
400	Barkby Beach to Gronant	Clwyd Estuary to Point of Ayr	Barrier Beach / Spit	6.19	0.60

The following information for each site is summarised in Appendix 1:

- location co-ordinates
- environmental setting
- morphological type
- nature of the back-beach
- management intervention methods / structures present
- main sediment type on the upper beach
- main sediment type on the lower beach
- area of bare shingle mapped from the most recent available aerial photographs
- area of vegetated shingle mapped from the most recent available aerial photographs
- conservation designations
- SMP2 management policy
- importance of the site for FCERM (both coastal erosion / coastal flooding risk and inland (river) flooding)
- importance for natural habitats and nature conservation
- importance as geomorphological features
- importance for historical and archaeological conservation
- importance for recreation
- importance in terms of economic or military use

The extent of bare shingle and vegetated shingle was estimated using the most recently available aerial photographs of each area and GIS software. The aerial extent values obtained provide only a snap-shot for the time the photography was acquired, and in some areas there is uncertainty due to variability in the proportions of sand and shingle present, but they do provide a useful indicator of the relative variation in shingle extent between sites.

3.3. Report structure

The remainder of the report is divided into sections which consider the key attributes of shingle and shingle features which need to be understood and taken into account in developing an appropriate shingle management strategy for FCERM which also takes into account other shingle interests. Section four examines the sedimentary properties of shingle. A review of shingle processes and landform features is provided in Section 5, while the nature of shingle vegetation and other conservation interests is summarised in Section 6. The FCERM significance of shingle in Wales is considered in Section 7 and available methods for the management of shingle for FCERM purposes are reviewed in Section 8. Section 9 presents the four case study examples and Section 10 presents conclusions and recommendations regarding best practice for shingle management in Wales. A series of tables listing the attributes of each shingle site is presented in Appendix 1.

4. The sedimentary properties of shingle

4.1. Particle size

Many engineers have used an upper size limit for shingle of 200 mm, which corresponds with the upper size limit of medium gravel in the British Standard Classification of Soils for Civil Engineering Purposes (BS:1377 Part 2, 1990). This size scheme uses a particle size scale based on the numbers 2 and 6 which was originally proposed by the Swedish chemist and agricultural scientist A.M. Atterberg (1905), and which has since been widely adopted by geotechnical engineers across the world (Figure 2). However, most earth scientists have used an alternative size classification scheme based on size intervals of root 2, developed by the American geologists J.A. Udden (1914) and C.K. Wentworth (1922). By reference to the most recent variant of this scheme (Pye & Blott 2012), 'shingle' is defined here as ranging in size between 2 mm (the lower size limit of very fine gravel) and 256 mm (the upper size limit of small boulders; Figure 2).

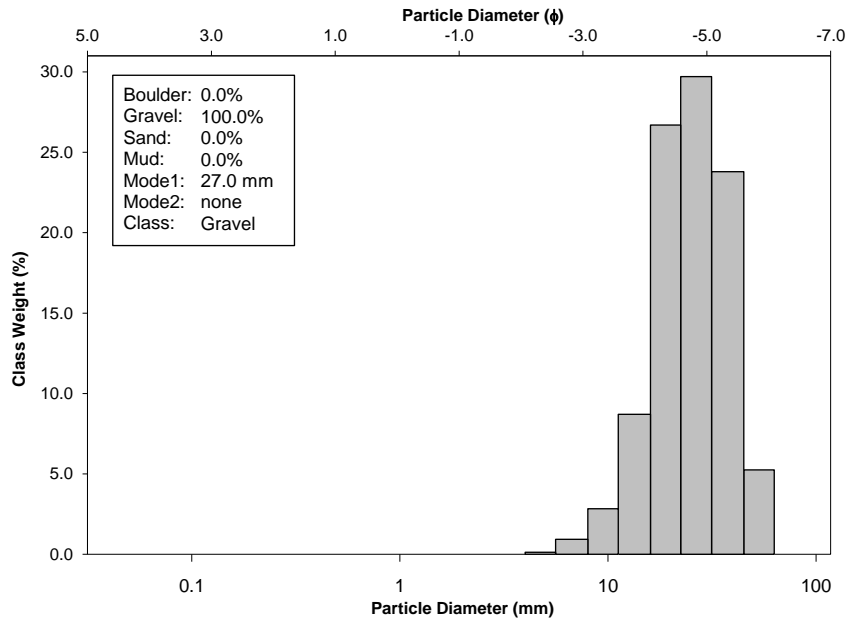

Some shingle deposits consist almost entirely of gravel size material (Figure 3a), but many contain significant proportions of sand and/or larger boulders (Figure 3b). Such 'mixed' sediments can be classified in terms of the proportions of gravel plus boulders, sand and mud, and described as 'shingle', 'sandy shingle', 'muddy shingle' etc. (Figure 4). Sediments composed predominantly of sediment particles (clasts) of any size larger than sand (>2 mm) are sometimes referred to as 'coarse clastic' (Orford & Carter, 1984, 1993).

The size distribution of shingle, like any other sediment, can be summarised using a number of quantitative measures. The median, or D50, size is often used in engineering literature as a measure of 'average' size, but this has little meaning in the context of markedly bimodal sediments such as that shown in Figure 3b. For this reason, the modal size (M1) or sizes (M1, M2, M3 etc) are more useful parameters to characterize the different grain populations present in bimodal or polymodal sediments. Measures of the range of sizes present, sometimes referred to as 'sorting', can be provided by the difference between selected percentiles of the distribution (e.g. D90- D10 or D75- D25), or by calculated statistical measures such as the second moment of the distribution or the 'phi sorting' measure of Folk & Ward (1957). A range of such summary statistics can be easily calculated using computer programmes such as GRADISTAT (Blott & Pye, 2001)

BS:1377 (1990)	ISO:14688 (2002)	Blott & Pye (2012)	Sieve size (mm or µm)
Boulders	Large Boulders	Megaclasts	2048 mm
		Very large boulder	1024 mm
		Large boulder	512 mm
		Medium boulder	256 mm
		Small boulder	128 mm
200 mm	200 mm		
Cobbles	Cobbles	Very small boulder	63 mm
60 mm	63 mm		
Coarse gravel	Coarse gravel	Very coarse gravel	31.5 mm
		Coarse gravel	16 mm

Figure 2 Particle size class terminology proposed by Blott & Pye (2012), based on a modification of Wentworth's (1922) grade scale, compared with that used BS:1377-2 1990 (BSI 1990) and ISO:14688-1 2002 (ISO 2002)

(a) Glanllynnau upper beach (Site 272)

(b) Afon Wen upper beach (Site 273)

Figure 3 Example particle size frequency histograms for samples of (a) clean upper beach shingle sediment from Glanllynnau), and (b) bimodal mixed sand-shingle sediment from Afon Wen, Gwynedd

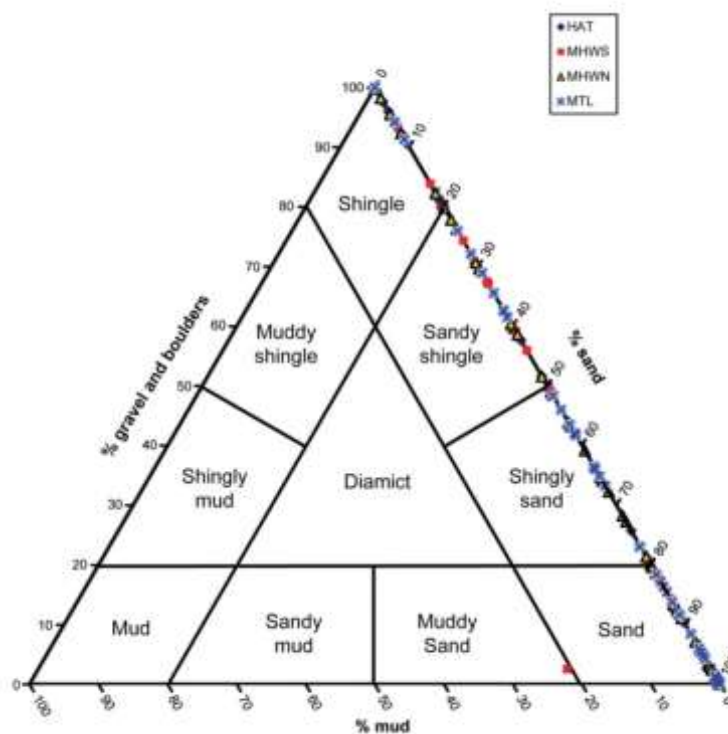

Figure 4 Example of a particle size ternary diagram, defined by the percentages of shingle (gravel and small boulders , 2 – 256 mm), sand (0.063 to 2 mm) and mud (<0.063 mm) in 256 beach samples collected by Gwynedd Council Coast Protection Department from beaches between Aberdovey and Morfa Dinlle in 2010-2011

Shingle deposits commonly display a high degree of variation in particle size with depth, across-shore, and alongshore (Figure 5). Active shingle beaches often show considerable variation in particle size over time, reflecting fluctuations in wave and tide conditions. For these reasons, it is important that sediment samples taken for beach characterization purposes are sufficiently large in size and number, and taken on a number of different occasions. In strategic sediment monitoring programmes whose purpose is to identify potential change over a number of years, samples should be taken at several positions along a number of cross-shore profiles at defined intervals, ranging from 6 months to 5 years depending on the rate of expected change). The minimum size of sample required depends on sediment size, and recommended minimum values are provided in BS1377 (BSI, 1990). For sampling of shingle beaches a standard sample size of approximately 25 kg has often been specified for coastal monitoring purposes. However, where beaches contain a high proportion of large cobbles and boulders meaningful sampling for laboratory analysis is impractical and estimates of clast size distributions can usually only be obtained by direct measurement in the field or from unmanned aerial vehicle (UAV) photographs.

1. VERTICAL VARIATION IN SURFACE PARTICLE SIZE (SECTION VIEW)

2. CROSS-SHORE VARIATION IN SURFACE PARTICLE SIZE (PLAN VIEW)

3. ALONG-SHORE VARIATION IN SURFACE PARTICLE SIZE (PLAN VIEW)

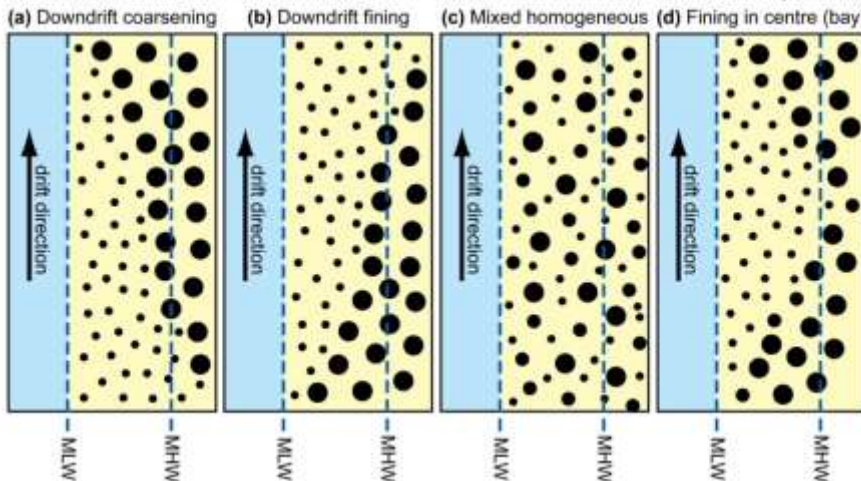

Figure 5 Schematic diagram showing patterns of variation in particle size potentially found on shingle beaches: (1) vertically; (2) cross-shore; and (3) along-shore.

4.2. Particle shape

The term 'shape' includes a number of different attributes of the three-dimensional geometry of a sediment clast or other object, including form, roundness and surface texture (Blott & Pye, 2008). 'Form' relates to the degree of equi-dimensionality of the clast, 'roundness' relates to the sharpness of corners and edges, and 'surface texture' relates to the degree of roughness or smoothness of the particle surface. Shingle clasts vary widely in shape, reflecting differences in their lithological composition, hardness and transport history. The broad-scale form (elongation and flatness) of shingle clasts is determined largely by the nature of the rocks from which the clasts were

derived, including bed thickness, fissility and degree of jointing. The degree of roundness and surface textural characteristics (roughness or smoothness is determined partly by the method of clast formation, partly the material hardness, and partly by the degree of abrasion experienced during transport.

Clasts which have experienced only a short period of water-borne transport are commonly angular or sub-angular, while clasts which have previously experienced length periods of fluvial or fluvio-glacial transport, or which have been exposed to wave action for a long period in the surf zone, are often relatively well rounded. Clasts composed of limestone, sandstone and slate become rounded much more quickly than granite or gneiss. Cross-shore zonation in particle shape, as well as size, is often seen on shingle beaches, but although both cross-shore and alongshore patterns can show significant change over time due to fluctuations in wave, tide and current conditions (Bluck, 1967, 1999; Orford, 1975; Williams & Caldwell, 1988).

Hard, dense materials such as flint, chert, vein quartz, granite and greywacke usually develop smoothly polished surfaces as a result of abrasion, whereas softer materials such as limestone, Chalk and un-metamorphosed sandstone usually have rougher surface textures.

Particle shape, in addition to size, can have a significant influence on the mechanism and rate of clast movement when exposed to wave and current influence. In general, equi-dimensional, well-rounded and smooth surface clasts are moved more readily by fluid motion than non-equidimensional, angular and rough-textured clasts.

4.3. Sources and lithological composition of shingle

The main sources of coastal shingle in Wales include:

- Glacial till exposed in coastal cliffs, the intertidal zone or on the sea bed
- Rocky coastal cliffs and shore platforms
- Relict coastal and/or marine shingle accumulations
- Biogenic production (shells, fragments of Sabellaria reef etc)
- Quarry and mine waste
- Rip-rap and rubble placed as ad-hoc shore protection
- Degraded concrete sea defences
- River-transported sediment from the hinterland
- Imported shingle and cobble from inland quarry sources used for beach nourishment
- Imported shingle and sand from offshore sources used for beach nourishment

Wave reworking of glacial deposits is an important source of shingle on the coasts of North Wales, Anglesey, Cardigan Bay and Pembrokeshire. Often the gravel and boulders from such sources show a wide range of lithological types, including igneous, metamorphic and sedimentary rocks representing distant as well as local sources (e.g. Figure 6). The clasts are often angular or sub-angular unless they have experienced significant exposure to wave action and associated abrasion (Figure 7).

Figure 6 Compositionally heterogeneous mixture of cobbles and pebbles sourced primarily from glacial till cliffs, Hen Borth, Anglesey

Figure 7 Upper beach formed of sub-angular cobbles and pebbles derived mainly by wave reworking of local glacial moraine deposits exposed in the intertidal zone, north end of Whiteford Sands, Gower

Where reworking of glacial deposits has not provided an important source of material, shingle beaches usually contain a narrower range of lithological types

which reflect geological exposures in nearby cliffs, intertidal rock platforms, up-drift sedimentary formations or neighbouring river catchments. For example, many of the shingle beaches in Cardigan Bay around Aberystwyth consist largely of clasts of local Silurian greywacke (Figure 8), while the shingle beaches on the North Wales coast around Llandudno and Conwy contain a high proportion of locally derived Carboniferous limestone clasts.

Figure 8 Rounded clasts of hard Silurian greywacke and vein quartz at Borth, Ceredigion, derived mainly from the cliffs around Aberystwyth. Note also the rounded clast of concrete in the right-centre of the photograph

In some localities, including Pwlldu Bay, Morfa Conwy and around Llanelli, tipping of quarry waste, industrial slag, and degraded sea defence structures have provided significant local sources of shingle (Figure 9 & Figure 10). Elsewhere, angular quarried rock has been placed on the beach specifically for FCERM purposes (Figure 11).

Figure 9 A barrier beach / barrier spit complex formed substantially of limestone quarry waste, Pwlldu Bay, Gower

Figure 10 Fringing shingle upper beach composed of reworked slag, brick and concrete, east of Burry Port

Figure 11 Angular rock (mainly limestone with some sandstone) placed for FCERM purposes at Llanfairfechan, North Wales

Gravel-sized clasts of recent biogenic origin (bioclasts) are found on many shingle beaches in Wales but usually represent only a small percentage of the total material. Accumulations of intact and broken shells are found fairly frequently on the upper parts of shingle and mixed beaches, especially after storms, but 'chenier' ridges composed largely of shell, of the type found in parts of southeast and southern England (e.g. Richards & Pye, 2001), have not been reported from Wales.

Much of the shingle now found on the Welsh coast, as in other parts of the UK, was moved landwards from the nearshore sea bed by wave action during early to mid-Holocene marine transgression. The process of landward migration of shingle beaches and barriers continues today, in response to storms and rising sea level, but at a slower pace than in the past. Many of the available offshore sources of shingle have now been exhausted, and the natural rate of new sediment supply to most shingle beaches and barriers is low. A few exceptions are found close to sections of rapidly eroding cliffs.

5. Shingle processes and landforms

5.1. Movement of shingle by waves and currents

In most areas around the Welsh and English coast, tidal current speeds close to the sea bed are not sufficiently strong on their own to move clasts larger than very fine gravel (although there are local exceptions where unusually high current velocities occur), and most shingle transport is accomplished by waves and combined wave / current action. The natural forward motion of swell waves and low amplitude storm waves, which have a relatively low height to wavelength ratio (low steepness) tends to move shingle towards the shore, provided the water depth is sufficiently shallow for waves to touch bottom. In the beach surf zone, forward wave motion under non-storm conditions is often capable of moving both gravel and sand towards the shore, but off-shore directed return currents (backwash) are capable only of moving finer particles, leading to a concentration of shingle around the high water mark. However, during severe storms, when nearshore waves typically have greater height and steepness, shingle can be combed down the beach-face and moved offshore where it accumulates as nearshore bars or shingle spreads. Unless the sediment is moved far enough offshore to lie below the fair weather wave base, or is moved alongshore and out of the system, shingle eroded from a beach during storms is gradually moved back onto the beach by swell waves and minor storm waves.

Shingle beaches are typically highly dynamic, and both the beach form and distribution of different clast sizes can change quickly in response to forcing processes. In high energy coastal settings, medium boulders, large boulders and even very large boulders may be moved by wave action. During the motion of mixed sediment sizes, larger particles show a tendency to move towards the surface while finer particles show a tendency to move downwards, leading to a coarsening –upwards pattern of grain sizes. As the coarse particles on the surface are more exposed to fluid forces, under some circumstances they may travel laterally at a faster rate than the underlying finer sediments, a process known as ‘overpassing’ (Isla, 1993).

5.2. Swash and drift aligned beaches

Shingle beaches are sometimes defined as being ‘drift aligned’ or ‘swash aligned’. Drift-aligned beaches are relatively straight and are characterised by high rates of alongshore sediment transport, driven by wave crests approaching obliquely to the shore, and in favourable situations fed by a supply of shingle at the up-drift end a sediment transport cell. Alongshore variations in wave energy conditions and local coastal orientation can cause variations in the alongshore transport rate, leading to crenulations in the plan form of the beach. Areas where the alongshore sediment transport rate slows significantly are likely to see accumulation of sediment, forming local sections of wider beach, progradational beach ridge plain or even a cusped foreland (‘ness’). By contrast, areas with locally enhanced sediment transport rate are

likely to see beach narrowing and erosion of shingle ridges, dunes or cliffs behind the beach, sometimes forming a shallow bay.

Swash-aligned beaches can be relatively straight where the dominant wave approach direction is almost perpendicular to the shore, but more commonly they have an embayed plan form, flanked by headlands, which is in quasi-equilibrium with the crests of breaking waves approaching the shore. Periodic (e.g. seasonal) changes in wave approach direction may cause temporary movement of sediment from one end of the embayment to the other, but net rates of alongshore sediment transport in any direction are low, especially where the flanking headlands effectively form a closed sediment 'compartment'. In situations where the supply of sediment to a length of coast is reduced e.g. through natural exhaustion or construction of coast protection or harbour entrance works, an initially drift-aligned shore may break down into a series of self-contained swash-aligned embayments (Pethick *et al.*, 2003).

5.3. Types of coastal shingle accumulation

5.3.1. Cross-shore distribution of shingle

Coastal shingle accumulations can be divided into a number of types depending on their environmental setting:

- Subtidal accumulations
- Intertidal accumulations
- Supratidal accumulations

Subtidal accumulations may represent relict or partially reworked river, fluvio-glacial or beach deposits, formed at a time of lower sea level during the Quaternary. Reworking of material from such sources, and from glacial till exposed on the sea floor and in coastal cliffs, has in some areas led to the formation of subtidal and intertidal shingle banks and shingle lag deposit formed when waves and currents selectively remove sand and mud. Such lag deposits may form thin sheets over wide areas of the sea bed or form channel infill deposits.

Intertidal shingle deposits may take the form of mobile gravel bars, mega-ripples, gravel dunes and gravel sheets, or immobile (sometimes cemented) lag deposits (e.g. Figure 7 & Figure 12). The latter are most commonly found on the mid or lower parts of the foreshore (the zone between the mean low water mark and the mean high water mark). Many such deposits are formed as lags during the process of landward barrier recession. In some instances the exposed mid or lower foreshore gravel is continuous with the upper beach shingle berm but is buried by a relatively thin veneer of mobile sand.

Figure 12 Mid-foreshore lag deposit composed of infrequently moved small boulders and shingle, Kenfig, South Wales

Three main types of marine shingle beach can be identified on the basis of cross-shore sedimentological variation (Pye, 2001):

Type 1 - beaches dominated by shingle down to mean low water level

Type 2 - beaches with an upper beach face and storm ridge composed of shingle and a lower beach composed largely of sand, although patches of shingle may also be present (in some instances a rock platform rather than sedimentary lower beach may be present)

Type 3 - beaches where mixtures of shingle and sand occur across most or all of the intertidal profile.

Type 2 beaches are the most common in Wales, although following severe storms mixtures of sand and gravel are often seen across a large part of the foreshore (Figure 13).

Figure 13 Upper beach and storm beach ridge composed of shingle at Pensarn, North Wales (photograph taken close to time of high tide)

5.3.2. Shingle features classified on the basis of plan form

Shingle beaches and storm beach ridges can also be classified in terms of their coastal setting and the plan form of the shingle accumulation. A number of previous authors (Oliver, 1912; Chapman, 1976; Randall, 1977a; Sneddon & Randall, 1993; Doody, 2001) recognized five types, namely (a) fringing beaches, (b) spits, (c) bars (or barriers) (d) apposition beaches (or cusped forelands) and (e) barrier islands. In this study six main types (A to F) and a number of sub-types are identified on the basis of plan morphology (Figure 14). Most of can be found in open coast, large embayment and estuarine settings, although tombolos, beach ridge plains, strand-plains, delta fans and forelands are very rarely found in estuaries.

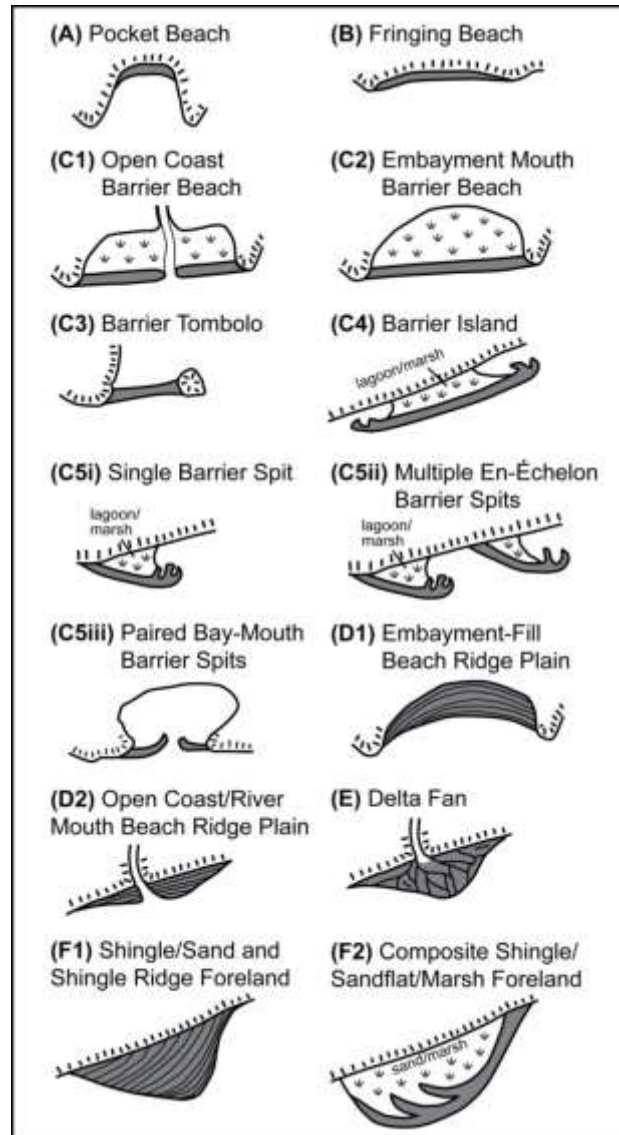

Figure 14 Schematic representation of the main morphological types of coastal shingle

5.3.2.1. Pocket beaches

Shingle pocket beaches are usually of short length (< 1 km) and occur at the head of a relatively small embayment which is deep relative to its width. In Wales they most commonly occur on indented sections of rocky open coast (Figure 15), but they can also occur within estuaries and tidal inlets. Although they sometimes block the discharge of small streams and may provide protection against wave attack on human infrastructure behind the beach, most pocket beaches are backed by non-developed rising ground and are of low FCERM significance. The shingle may be restricted to a narrow zone close to the high water mark or may extend across a wide area of the foreshore, partially and/ or periodically buried by sand.

Figure 15 Aerial photograph of Nolton Haven, Pembrokeshire. An example of a pocket beach with shingle upper beach and wide sandy lower beach

5.3.2.2. Fringing beaches

Fringing shingle beaches are the most common type found in Wales, occurring on the open coast, within embayments of many different sizes, and within estuaries such as the Dee and Severn. The size of the shingle accumulation can vary widely, ranging from a narrow, relatively thin strip to a wide, high, ramp-like accumulation. Fringing shingle beaches vary in length from a few hundreds of metres to several kilometres, often forming a ramp or berm in front of a cliff, sand dune or artificial sea defence (Figure 16, Figure 17, Figure 18 & Figure 19), and fronted by a lower, flatter beach which is predominantly sandy. In some instances the active beach face, which is regularly worked by waves, grades into a storm beach ridge with a clearly defined crest. The ridge itself may provide a barrier to flooding but fringing beaches which occur in front of coastal defences most commonly have FCERM significance because they help

to dissipate wave energy, reduce the risk of wave overtopping and reduce the required design standard of the man-made defence behind.

Figure 16 Fringing shingle upper beach in front of sand dunes at Aberdovey

Figure 18 Example of a narrow fringing shingle upper beach, Amroth, Carmarthenshire 2017

Figure 19 Example of a relatively wide fringing shingle and boulder beach in front of concrete sea defences and Aberthaw Power Station, both partially built on top of shingle

5.3.2.3. Barrier beaches

Barrier beaches usually consist of a laterally extensive shingle or sand beach and shingle ridge which separates the sea from low and potentially floodable land behind; it may be broken at intervals by small streams. An example is found between Criccieth and Craig Ddu in Tremadoc Bay (Figure 20).

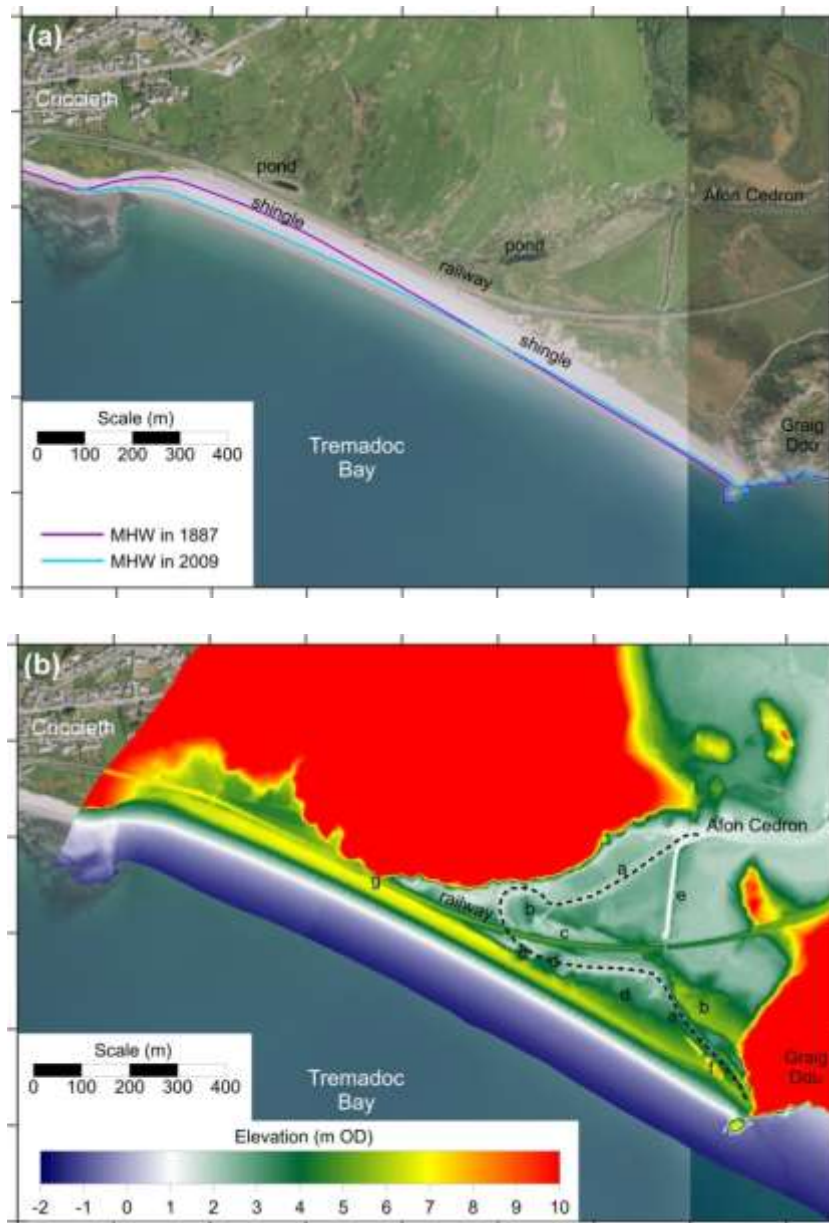

Figure 20 Aerial photograph (a) and Composite LiDAR DTM (b) of the Criccieth – Craig Ddu shingle barrier beach with Cambrian Coast railway line immediately behind. The Afon Cedron once reached the sea towards the western end of the barrier but now discharges through an artificial cut at the eastern (up-drift) end. Excavated shingle forms two vegetated NW – SE oriented mounds on the west side of the cut. The shingle ridge is subject to localised wash-over during storms and any transgressive shingle reaching the Cambrian Coast railway line is removed reactively

Where a barrier joins an island with the mainland, it may be described as a *barrier tombolo*. There are few such examples in Wales. A short tombolo, now largely covered by commercial buildings, links a glacial till outlier with the mainland at Gallow's Point on Anglesey, but does not form a barrier. The heavily modified shingle and sand ridge to the west of Carreg yr Imbill near Pwllheli could arguably be called a barrier tombolo, although the western half is more typical of a barrier beach (Figure 21).

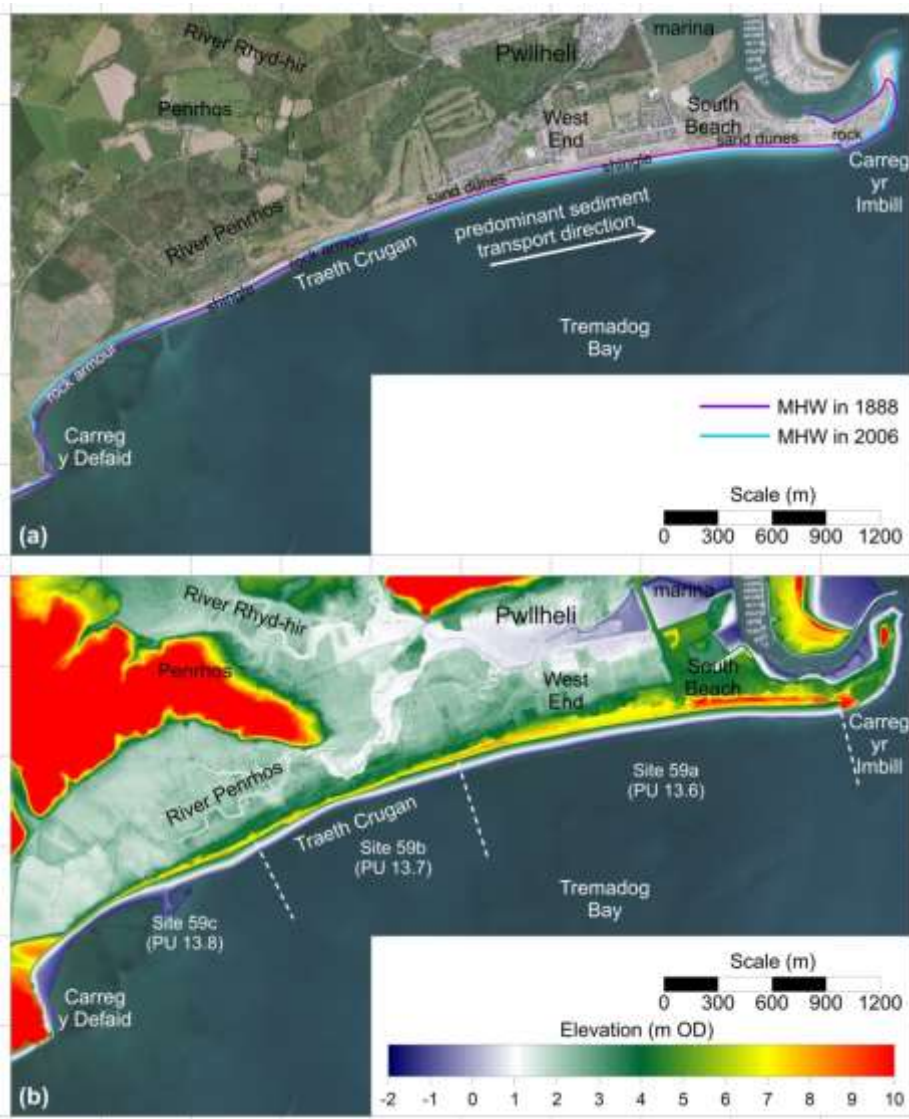

Figure 21 Aerial photograph (a) and LiDAR DTM (b) of the Carreg y Defaid – Carreg yr Imbill barrier in northern Tremadoc Bay. At its western end the barrier is low and consists of relatively coarse shingle ridge which has been reinforced with rock armour; at the eastern end near the former island of Carreg yr Imbill, the barrier is much wider and consists of dunes overlying mixed shingle and sand. The section of barrier between South Beach and Carreg yr Imbill could arguably be classified as a tombolo, while the section between Carreg yr Imbill and the entrance to Pwllheli harbour has the form of a spit. Aerial photography flown 2013-14, composite LiDAR DTM flown 2013-15

If a barrier is attached to the mainland only at one end it may be described as a *barrier spit*. Open coast barrier spits can be single features or form part of an 'en-echelon' series of multiple spits (not found in Wales), with shallow lagoons or areas of intertidal marsh behind. Single or paired spits can also be found at the entrance to, or within, estuaries and bays.

There are a considerable number of barrier spits in Wales; examples are found at the mouth of Afon Dwyfor in Tremadoc Bay (Figure 22), at Tanybwlch at the mouth of the River Ystwyth in Cardigan Bay (Figure 23) and at Ro Wen (Fairbourne) at the mouth of the Mawddach estuary (Figure 24). Although barrier spits do not entirely act as a barrier to tidal flooding of the areas behind, the narrow nature of the associated inlets reduces storm surge and wave ingress.

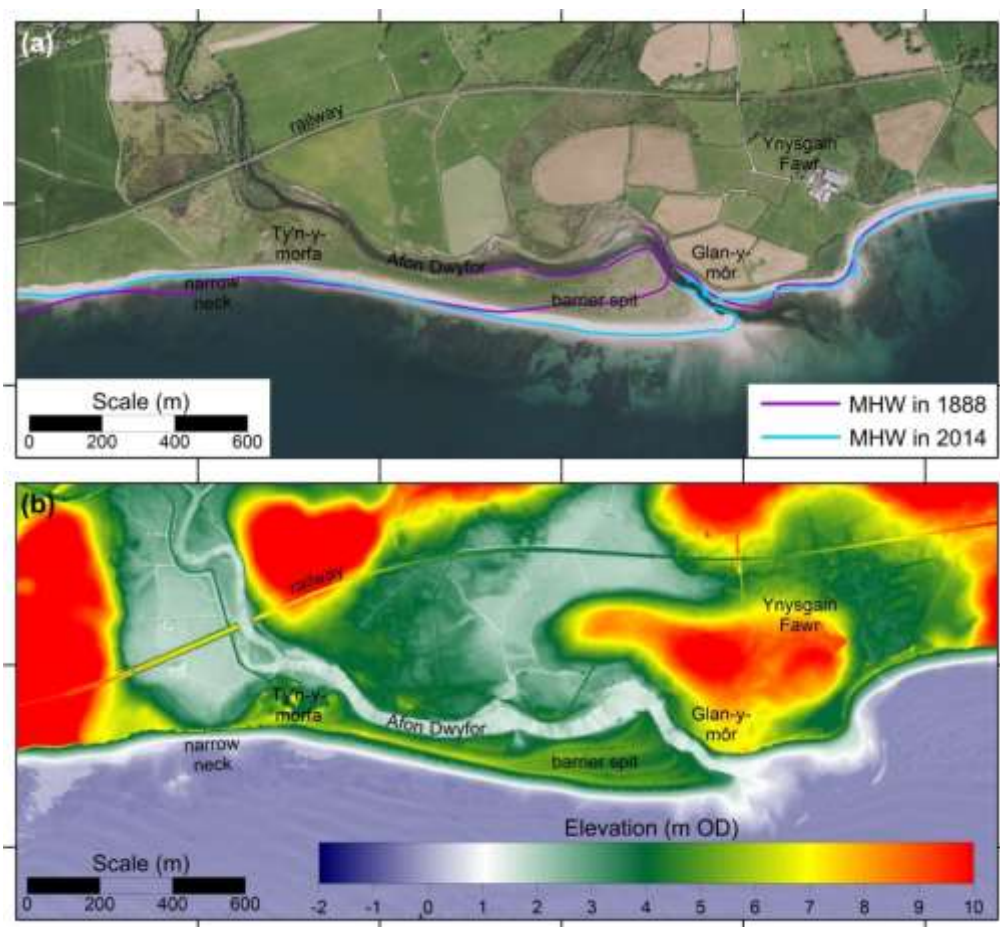

Figure 22 The Afon Dwyfor barrier spit, Tremadoc Bay. Note the very narrow nature of the spit at its neck. (a) Aerial photography flown 2013-14; (b) LiDAR DTM flown 2014

Figure 23 The Tanybwllch barrier spit at the mouth of the River Ystwyth. Note that the river has cut into the back side of the ridge as it has moved landwards, requiring placement of rock armour on the outside meander bend. The Tanybwllch barrier now receives very little new shingle from the cliffs and fringing beaches to the south and the southern end of the barrier has narrowed considerably in recent decades, despite rock armour protection. Long-term maintenance of the barrier in its present form was judged by Pethick et al. (2003) to be unsustainable. (a) Aerial photography flown 2013; (b) LiDAR digital terrain model, flown 6th to 13th January 2012

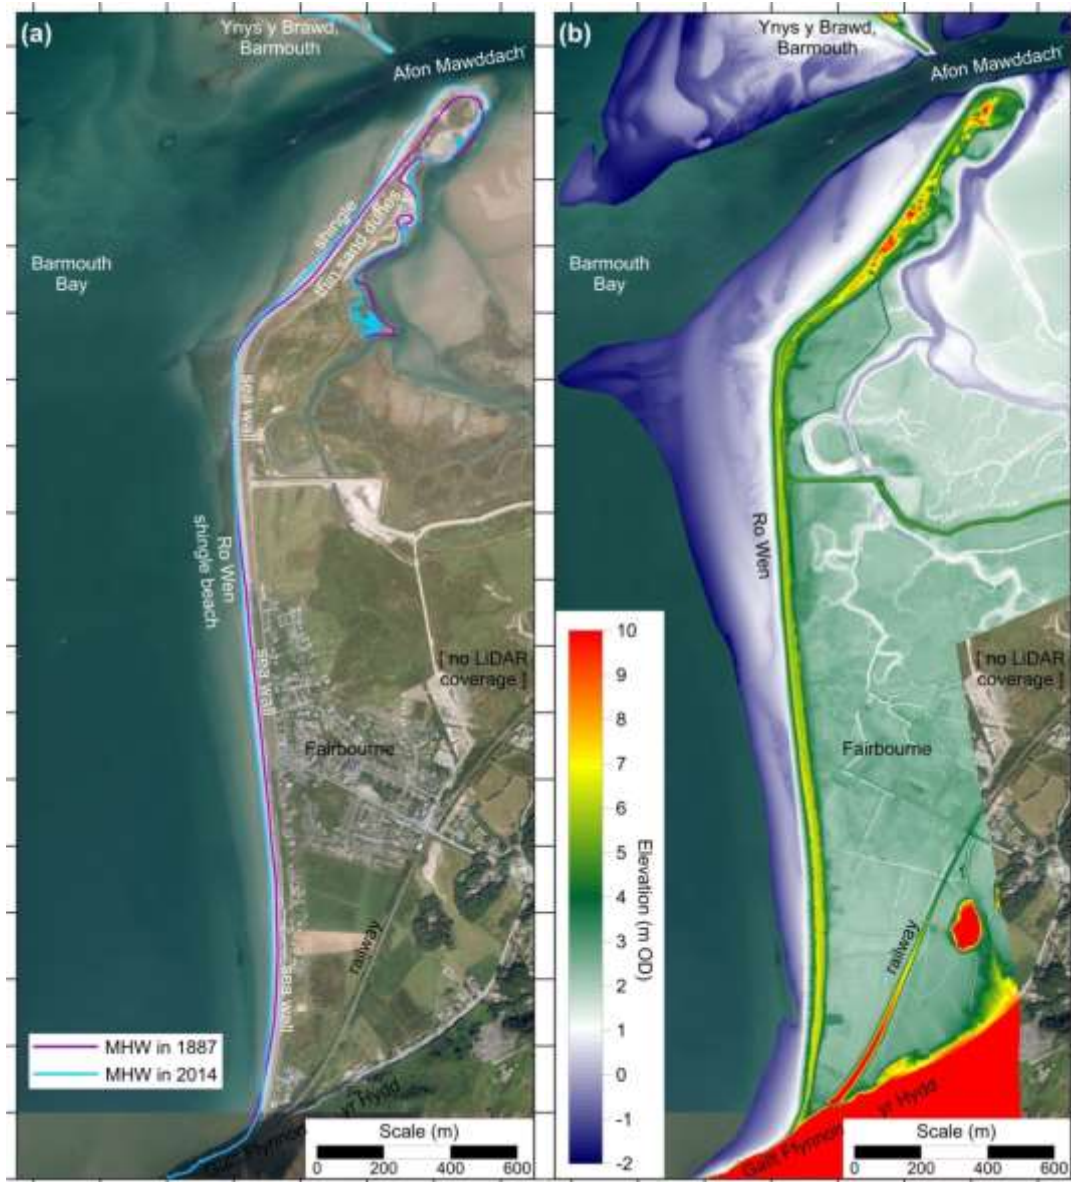

Figure 24 Ro-Wen (Fairbourne) Spit (buildings removed). At the extreme southern end near the Friog cliffs the barrier is very narrow and composed of coarse shingle and cobbles; much of the rest of the west-facing part of the barrier has a uniform width and consists of smaller shingle and cobbles, while the northwest-facing northern section is composed of finer shingle and sand capped by dunes. Much of the ridge is backed by concrete defences which provide additional coastal flood protection for the village, Fairbourne light railway and access road to the Barmouth ferry. Concerns about diminution of the shingle / cobble upper beach at Friog have led to proposals to import 4000 tonnes of cobble from an inland quarry source. (a) Aerial photography flown 2013; LiDAR DTM flown 2009

The Esgair Cemlyn shingle ridge on Anglesey was initiated as a barrier spit but is now attached at its northern end to an artificial mound and weir structure which spans the entrance to Cemlyn Lagoon (Figure 25). The ridge receives little new sediment and is migrating slowly landwards by washover during storms (Pye & Blott, 2010, 2016).

Figure 25 Esgair Cemlyn, Anglesey: an example of a relatively narrow shingle barrier which originated as a spit with a shallow tidal lagoon and intertidal flats behind, but which is now attached to an artificial mound and weir which regulates water levels in the lagoon

5.3.2.4. Beach ridge plains

Multiple beach ridge plains form where the medium to long-term beach and nearshore sediment budget is positive, allowing seaward accretion of new beach ridges over periods of decades to millennia (e.g. Billy et al., 2015). Short periods of shoreline erosion often punctuate the longer term progradation trend. The ridges may form within an embayment which acts as a 'trap' for sediment transported from alongshore or offshore sources, or on the open coast where large amounts of sediment are supplied by rivers and where wave processes are effective in reworking the sediment. Development of wide beach ridge plains is favoured by relatively low rates of sea level rise or falling relative sea level. Where sea level shows a net upward long-term trend, ridge crests often increase in elevation towards the active shore. If rivers supply large amounts of sediment but wave energy is insufficient to rework it completely, a delta fan may develop.

Shingle beach ridge plains are rare in Wales. On the North Wales coast a series of low shingle ridges, capped by a thin layer of windblown sand, formed within a shallow embayment to the east of the Llanddulas headland, but for the past three decades the shore has been eroding (Lee, 1995; Figure 13 & Figure 26).

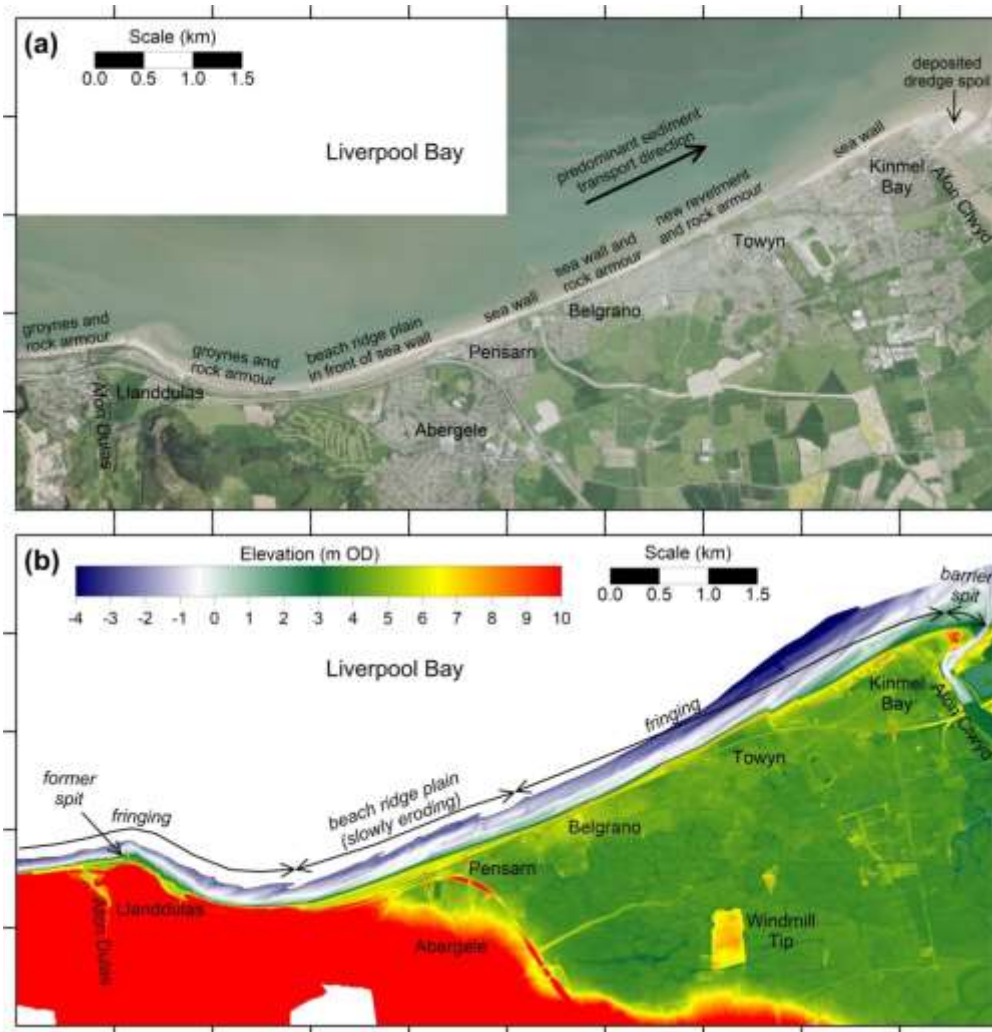

Figure 26 The heavily man-modified coast between Llanddulas and Kinmel Bay, North Wales, including the progradational embayment-fill shingle beach ridge plain between Llanddulas and Pensarn. (a) Aerial photography flown 2013-14; (b) Composite LiDAR DTM, flown 2007-2014

5.3.2.5. Fan delta

Fan delta shingle accumulations are found where high energy rivers or streams discharge relatively large amounts of mixed sediment into the coastal zone. Sand and finer sediment is dispersed away from the river mouth by wave and current action faster than the gravel-sized material, leading a coarse-grained lag accumulation. An example occurs at where the Afon Aber discharges into the sea between Bangor and Llanfairfechan (Figure 27).

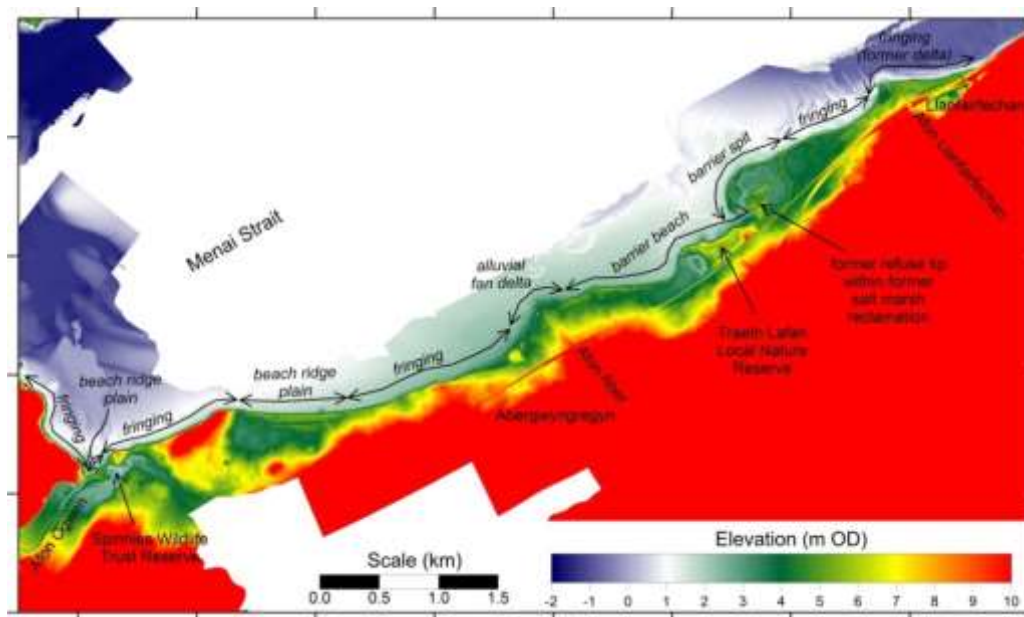

Figure 27 Fringing, barrier beach, barrier spit and alluvial fan delta types of shingle accumulation on the heavily man-modified coast between Afon Ogwen and Llanfairfechan. Composite LiDAR DEM, flown 2007-2014

5.3.2.6. Forelands

A Foreland or 'ness' is a convex or broadly triangular accumulation of sediment which project seaward from the general line of the coast. Two types may be distinguished: (a) those which are formed entirely of shingle or sand and shingle ridges, and (b) those which have an outer shingle 'skeleton', often spit-like in plan form, behind which are areas of sandy intertidal flats or saltmarshes. There are currently no examples of pure shingle or sand and shingle ridge forelands in Wales, although composite forelands which include shingle elements are found, for example at Morfa Conwy (Figure 28).

Figure 28 A composite sand and shingle foreland at Morfa Conwy

5.3.3. 46 Classification based on sedimentary architecture and morphological evolution

Shingle features can also be classified on the basis of their sedimentary architecture and medium to long-term morphological development (Figure 29).

Stable shingle ridge structures (Figure 29a) display little net change in their lateral position on timescales of decades to millennia, although the beach face and ridge crest naturally displays short-term variability in response to changes in wave and tide conditions. This type of ridge is often located at the interface between marine sediments and terrestrial coastal plain sediments or underlying rock, and is associated with low rates of sediment supply and/ or small net changes in the local beach sediment budget. Under conditions of slowly rising sea level as at present), the ridge crest may increase slightly in height and width as the ridge moves landward. An example is provided by the Newgale shingle ridge in Pembrokeshire (see case study example below).

Regressive barriers (Figure 29b) usually consist of a single ridge which moves landward over periods of decades to millennia, 'rolling back' over back-barrier marsh, lagoon or freshwater alluvial sediments. Back-barrier sediments are often exposed on the upper part of the foreshore to seaward of the ridge. This type of barrier is usually found in areas of negative beach and nearshore sediment budget (due to low rates of supply and/ or a high rate of alongshore transport, onshore movement of deep water channels, or relatively high rates of sediment drift). There are many examples where this situation is found around the Welsh coast, although in places the recession of the barrier has been arrested over the past 100 – 150 years by coast protection measures (e.g. at Borth, Abergele, Rhyl).

Prograded barriers (Figure 29c) typically display multiple shore-parallel ridges, sometimes cross-cutting, which have developed in a net seawards direction over time. They occur in areas of long-term net sediment accumulation, either within embayments where sediment transported from alongshore or offshore becomes trapped, or where there is sudden reduction in alongshore sediment transport rate.

In drift-aligned systems it is not uncommon to find regressive barrier behaviour and morphology at the up-drift end of the sediment transport cell, stability in the centre, and progradational behaviour and morphology at the down-drift end. This situation is likely to develop if there is a reduction in the rate of sediment supply from neighbouring sections of coast up-drift, in which case the shoreline orientation may show a tendency to change from drift-alignment to swash alignment, provided sediment is trapped at the down-drift end (Orford et al., 2002).

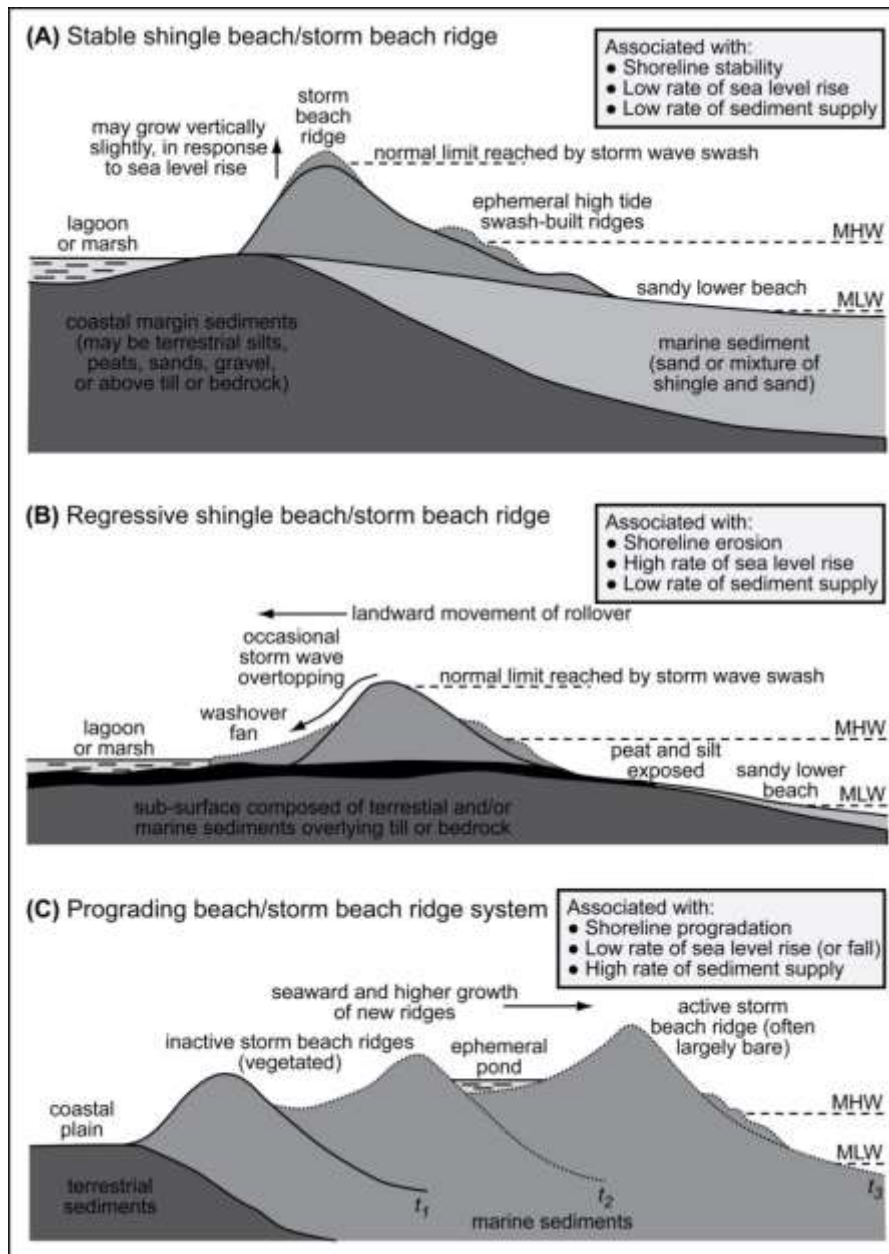

Figure 29 Three types of shingle ridge structures which display differing stratigraphic architecture in response to contrasting histories of morphological development

5.4. Response of shingle barriers to rising sea level

The response of shingle barriers to sea level rise is dependent on a number of factors:

- the local sediment budget, which determines whether a shingle beach / ridge complex can grow vertically, seawards, or move landwards keeping pace with sea level rise
- the rate of sea level rise
- the accommodation space available for a shingle beach / ridge system to adjust by moving landwards

- the nature of, and any changes in, the wave climate, particularly storm wave climate, which determines the potential for sediment to move onshore, offshore or alongshore.

Owing to geographical variation in these factors, the response of individual shingle features to sea level rise may be complex and there is likely to be considerable variation from one shingle feature to another. Prediction of the likely response therefore requires a detailed understanding of local process and sediment supply conditions, the surrounding terrain, and likely future rates of sea level rise.

Where there is flat or gently rising land lies behind a shingle barrier it should be able to migrate landwards by a process of 'rollover', but where the features are backed by high ground or artificial defences retreat is impeded and the features will be subject to 'shingle squeeze' (Doody, 2001a,b).

On gently upward sloping coastal plains the barrier may be able to move landwards and maintain a constant sediment volume under low to medium rates of sea level rise, without any increase in sediment supply (Figure 30a). However if the barrier moves landward across flat or downward sloping ground it is likely to become drowned unless there is a significant increase in sediment supply (Figure 29b). Locally, the sediment supply may be sufficiently large to allow a beach / barrier system to prograde seawards and increase in crest height, despite sea level rise. In Wales, this is only likely to be possible at the distal ends of some barrier spit systems which are fed by alongshore movement of sediment eroded from up-drift areas (e.g. at Gronant, east of Prestatyn).

In situations where a fringing shingle beach ridge is squeezed against high ground or sea defence, it will only be possible to maintain constant morphology and sediment volume above a new higher sea level if there is significant additional sediment supply (Figure 30c). If additional sediment is not available to maintain a constant nearshore and intertidal / supratidal coastal profile, greater water depths, larger nearshore wave heights and greater wave reflection are likely to result in net offshore movement of shingle and gradual wasting of the feature. Unless large-scale beach and nearshore sediment nourishment is undertaken, this situation is likely to increasingly affect the majority of fringing and pocket shingle beaches in Wales over the coming decades.

At times during the early to mid-Holocene when sea level was rising at 5-10 mm/yr or more, barriers in some parts of the world are known to have been 'drowned' and left as relict ridges on the nearshore sea bed as the shoreline moved rapidly landwards, a process known as over-stepping (Forbes *et al.*, 1991; Mellett *et al.*, 2012). However, no definite examples of such drowned barriers have so far been identified around the Welsh coast, and forecast rates of future sea level rise in the next hundred years are unlikely to be sufficiently high for overstepping and drowning of major Welsh shingle barriers.

Figure 30 Schematic diagram showing the evolution of swash-aligned shingle barriers in response to sea level rise and dependence on sediment supply

The response of swash-aligned bay-barriers to sea level rise is likely to depend partly on the magnitude of sediment supply and the degree to which the sediment compartment is 'closed' or 'open' (Figure 31). In a closed sediment compartment situation, the barrier may be able to roll back and maintain its relative elevation if the embayment narrows in a landwards direction, or the level of the ground behind the barrier rises (Figure 31a). However, if the sediment compartment is partially open and there is leakage of sediment from the embayment the barrier is likely to become narrower and lower relative to the tidal frame as sea level rises, eventually leading to breach and tidal inlet formation (Figure 31b).

Figure 31 Schematic diagrams of barrier rollover in closed and semi-open sediment compartments

6. Shingle vegetation and other conservation interests

6.1. Requirements for establishment of shingle vegetation

For vegetation to become established on shingle the surface needs to be relatively stable (moved only every few months or years) and contain a proportion of fine material which can retain moisture. Due to its porous nature, shingle without fines above the water table does not retain water well, and most vegetation other than lichens and bryophytes cannot grow on it. The release and infiltration of organic matter from decaying seaweed and other vegetation assists the retention of moisture and allows a soil to develop in the surface layers of shingle over time. A spatial gradient of vegetation types and communities is usually seen on shingle formations, reflecting varying exposure and tolerance to salt spray, wave run-up, stability of the shingle surface and degree of surficial soil development (Oliver, 1911, 1912; Tansley, 1939; Scott, 1960; 1963; Randall, 1977b; Fuller, 1987).

Sneddon & Randall (1993a) and Randall & Sneddon (2001) recognized six main divisions of shingle vegetation classification, with a number of sub-types, which broadly follow a pattern of zonation from most landward to most seaward (Table 2). Sea kale (*Crambe maritima*) and sea campion (*Silene maritima*) are amongst the species which can tolerate salt spray and wave influence, and hence can occur on the seaward beach face down to the level of approximately mean high water spring tide level in sheltered settings such as the Menai Strait (Figure 32 & Figure 33). Higher up the beach and on the ridge crest, where there is greater shingle stability and greater accumulation of interstitial fine sediment, Sea Beet (*Beta vulgaris*), Sea Holly, (*Eryngium maritimum*) and Sea Thrift (*Armeria maritima*) are often found. On the highest and most stable parts of the ridge Yellow-horned Poppy (*Glaucium flavum*), a range of grasses and occasional shrubs may occur. In windswept settings and on very stable shingle surfaces extensive coverage of lichens or heathland vegetation may develop. Where shingle grades into sand dunes, saltmarsh, mudflat or saline lagoons a range of transitional habitats is created which include species more typical of dune and marshy environments.

Some of the rare pioneer and early successional stage plant communities found on shingle are unique to this substratum and are highly susceptible to disturbance (Low, 2007). Slow-growing bryophyte and lichen communities develop in stable surfaces with thin soils, and tend to be restricted to large shingle structures with very low levels of surface disturbance. They are very rare in Wales. Trampling disturbance is a particular problem for these communities and also for strandline pioneer communities (Scott & Randall, 1976, Randall, 1977b). Vehicle movements, including plant used in FCERM operations, can also be a problem. To facilitate continued development and survival of these communities, access needs to be restricted.

Table 2 Major shingle vegetation divisions ordered from most landward to most seaward (Randall & Sneddon, 2001)

1. Scrub communities	1a. <i>Prunus spinosa</i> communities 1b. <i>Rubus fruticosus</i> communities 1c. <i>Ilex europaeus</i> communities	
2. Heath communities	2a. Wet heaths 2b. Dry heaths	2bi. <i>Pteridium aquifolium</i> 2bii. <i>Calluna vulgaris</i> communities 2b.iii. Moss-rich communities
3. Grassland communities	3a. Saltmarsh-influenced grasslands 3b. <i>Agrostis stolonifera</i> grasslands 3c. <i>Arrhenatherum elatius</i> grasslands 3d. <i>Festuca rubra</i> grasslands 3e. Mixed grasslands 3f. Sandy grasslands	
4. Mature grassland communities	4a. Mature grasslands 4b. Less mature grasslands	4a.i. Mature grasslands – <i>Festuca rubra</i> 4a.ii. Mature grasslands – <i>Dicranum scoparium</i> 4a.iii. Mature grasslands 2b.i. Less mature grasslands pure shingle 4b.ii. Less mature grassland saltmarsh influenced <i>Arrhenatherum elatius</i>
5. Secondary pioneer communities		
6. Pioneer communities	6a. <i>Honkenya peploides</i> dominated communities 6b. <i>Senecio viscosus</i> dominated communities 6c. <i>Beta vulgaris</i> dominated communities 6d. <i>Raphanus maritimus</i> dominated communities 6f. <i>Silene maritima</i> dominated pioneer communities	

Figure 32 Example of pioneer vegetation development close to the MHWS line on a fringing shingle beach with low wave exposure, Menai Strait east side

Figure 33 Example of a slowly retreating vegetated shingle ridge, Pensarn, North Wales

Other types of shingle vegetation on shingle structures require varying degrees of management to prevent invasion by scrub and coniferous trees where shingle occurs in proximity to forestry plantations. Areas of *Calluna vulgaris* on shingle generally require low levels of grazing to maintain age and species diversity, although there is risk that grazing animals will raise nutrient levels in the surface soil and lead to vegetation change (Doody, 2001a).

6.2. Important vegetated shingle sites in Wales

As part of a Nature Conservancy Council (NCC) sponsored review of vegetated shingle habitats in Great Britain, Sneddon & Randall (1993b) identified 13 shingle sites in Wales which were judged to be of importance in terms of their vegetation communities (Figure 34). This assessment was based on discussions with NCC staff, a review of available background literature, examination of maps and aerial photographs and field visits during the period 1989-1990. As part of this study maps were prepared showing the distribution of major National Vegetation Classification (NVC) communities at each of the key sites. No further surveys have been conducted at a national scale in Wales since that time, and changes at most locations remain unquantified.

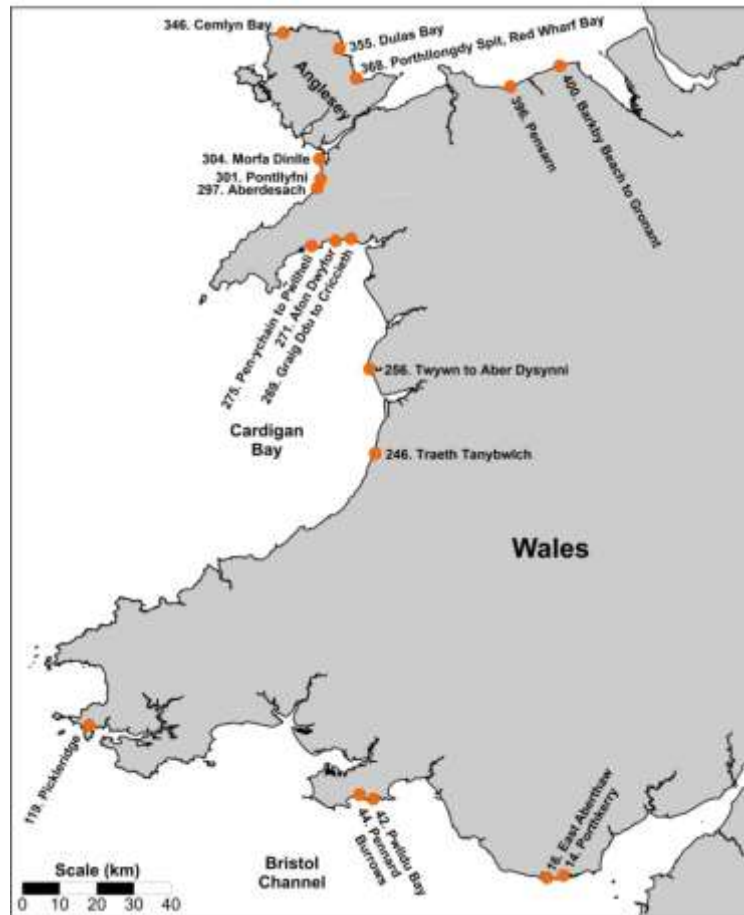

Figure 34 Sites in Wales identified by Sneddon & Randall (1993b) in terms of importance for vegetated shingle. Site numbers and names are those used in the present study

In a later assessment, Randall & Doody (1995) considered none of the shingle sites in Wales to be of National (UK) importance for vegetated shingle, although three sites (Cemlyn Bay, Traeth Tanybwch and East Aberthaw) were included in a list of “Other sites of significance”. Tanybwch, Cemlyn, Crabhall Saltings and Pwlldu were included in a list of the top 20 national sites for floristic diversity. Tanybwch and Crabhall Saltings were included in the top 20 list for floristic composition and size, but only one site, Pwlldu, made the top 20 list based on a combination of floristic, size and disturbance ranking.

There are seven shingle in sites in Wales which are located within Sites of Special Scientific Importance (SSSI) and where the citations make specific reference to shingle and/or shingle vegetation features (Figure 35). All seven were included in the lists of important sites prepared by Sneddon & Randall (1993b) and Stapleton (1996).

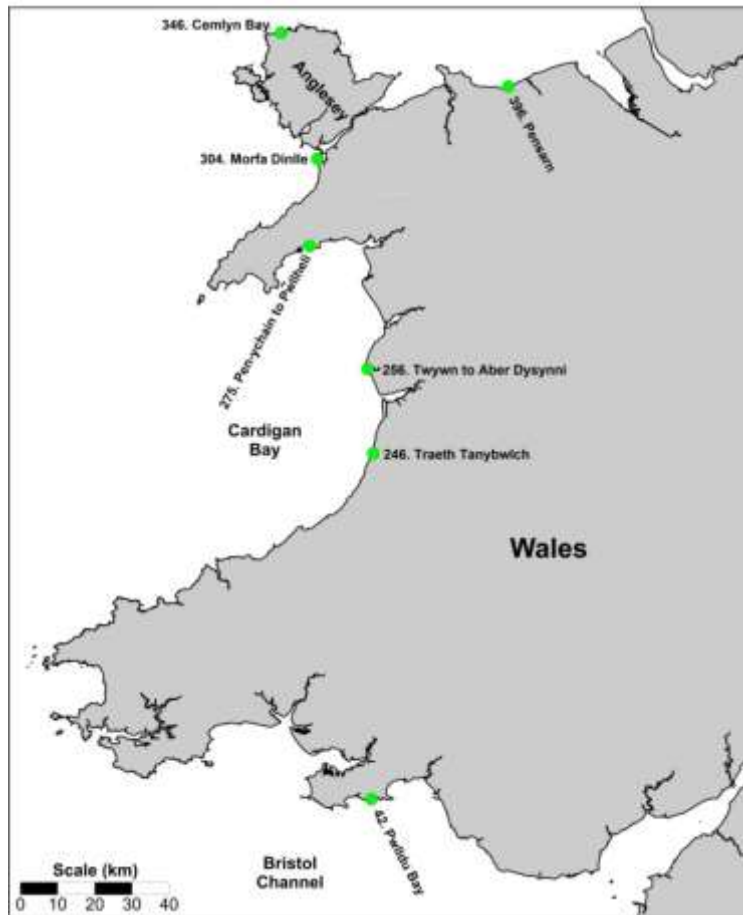

Figure 35 Shingle features within Sites of Special Scientific Interest and where the designation citation states that the shingle or vegetated shingle is a 'special' feature

Although more recent inventories of vegetated shingle have been compiled for England and Wales (Exegesis and Doody, 2009; Murdoch et al., 2014), no recent national assessment of vegetated shingle in Wales has been undertaken.

The pressures on shingle vegetation arise mainly from the following:

- heavy pedestrian visitor pressure, notably close to recreational beaches and caravan parks
- unrestricted vehicle access (off-road vehicles, quad-bikes and trail bikes)
- beach management operations, notably the movements of heavy plant

Measures which can be taken to reduce damage from pedestrians and unauthorised vehicles including fencing and provision of marked routes to the beach. Damage from beach management operations can be minimised by restricting plant movement to clearly defined access tracks and along the beach well below the drift line.

6.3. Other ecological conservation interests

A number of specialist invertebrate species are also associated with stable, vegetated or partially vegetated shingle (Morris & Parsons, 1993; Shardlow, 2001). These include the bugs *Rhopalus rufus* and *Monosynamma maritima*, the leafhopper *Aphrodes duffieldi*, the Dark Guest Ant *Anergates altratulus*, the Cuckoo Bee *Nomada ferruginata* and the Brown-banded Carder Bee (*Bombus humilis*).

Both vegetated and unvegetated shingle are also important for nesting and roosting birds, including Little Tern (*Sternula albifrons*), Arctic Tern (*Sterna paradisaea*) and Black-Headed Gull (*Chroicocephalus ribibundus*), although they are at risk from predators unless the sites used are located on islands and other inaccessible locations, or fencing protection is provided (Cadbury & Ausden, 2001). Important tern breeding sites on shingle include Cemlyn Bay on Anglesey and Gronant and Point of Ayr in North Wales.

6.4. Geomorphological conservation interests

In the mid-1990s the Institute of Estuarine and Coastal Studies (IECS) at the University of Hull was commissioned by the Countryside Council for Wales (CCW) to undertake an assessment of the geomorphological and hydrological status of the marine coastal shingle resource in Wales, in order to inform ecological and geomorphological conservation. This assessment included a literature review, consultation with maritime country and district councils, examination of 1:10 000 scale aerial photographs flown in 1992 and 1:25,000 scale Ordnance Survey maps, and field surveys at 20 selected sites (Stapleton, 1996; Figure 36).

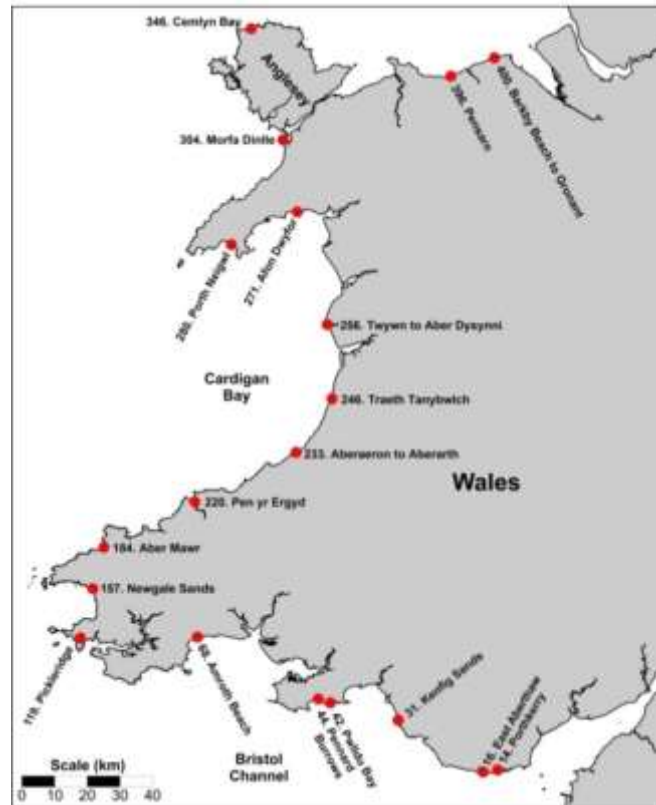

Figure 36 Important shingle structures in Wales identified by Stapleton (1996). Site numbers and names are those used in the present study

A further assessment of the geomorphological significance of a number of individual Welsh shingle sites was undertaken as part of the UK Geological Conservation Review (GCR). GCR Site Management Reports were prepared for sites in Wales which contain shingle (e.g. Mathews, 1997), but only a small number of sites were included in the national (UK) overview report (May & Hansom, 2003) as being of geomorphological and geological importance, either in their own right or as part of larger coastal landform complexes. These sites included Pwllidu, Ynyslas and Morfa Dinlle and Newborough Warren / Abermenai (May, 2003a,b,c,d).

In the present study, 49 of the 403 shingle sites identified sites have been judged to be of geomorphological significance, either in terms of area and nature of shingle features alone or shingle in combination with other features such as dunes, saltmarshes and lagoons (Table 3). Many of these sites have been modified by human activities to varying degrees but they retain important geomorphological interest features. Prior to coastal development and construction of coast protection structures in the 19th and 20th centuries, the number and frontage length of sites of geomorphological importance was much larger. However, significant areas have been lost or degraded during the past 150 years. For example, as long ago as the mid-1940s, Steers (1946) noted that “the whole length of coast between Llandudno to Point of Air is unfortunately spoiled in various ways”. Many of the original shingle (and also sand dune) features along the North Wales coast between Bangor and Prestatyn have indeed been lost or heavily modified. This is also the case at

many other shingle sites in South Wales and West Wales where hard defences have been constructed, including Amroth, Aberthaw, Fairbourne, Barmouth and Porthcawl.

Table 3 Shingle beaches and structures identified in this study as being of importance as individual geomorphological features or landform assemblages

ID	Localities	Policy Development Zone	Bare gravel area (ha)	Vegetated gravel area (ha)
13	Pebble Beach, Barry	The Knap to Watch House Beach	8.63	0.18

7. Flood and Coastal Erosion Risk Management Significance

7.1. Factors affecting FCERM significance

Although it has been recognized for many years that some shingle beaches, natural ridges and artificially maintained shingle embankments in Wales have considerable FCERM significance, there has been no previous systematic assessment of this aspect.

The degree of FCERM significance of a shingle feature (beach, ridge or multiple ridge structure) is related to the elevation of the hinterland, the size (crest elevation, width at MHWS elevation) of the shingle structure, the presence or otherwise of other coast protection / flood defence structures, and the value of the assets protected (Figure 37). Shingle beaches / ridges in front of high value assets (e.g. housing, industrial installations, power stations and transport infrastructure) are of greater FCERM significance than those which protect farmland without additional assets (Figure 38 & Figure 39).

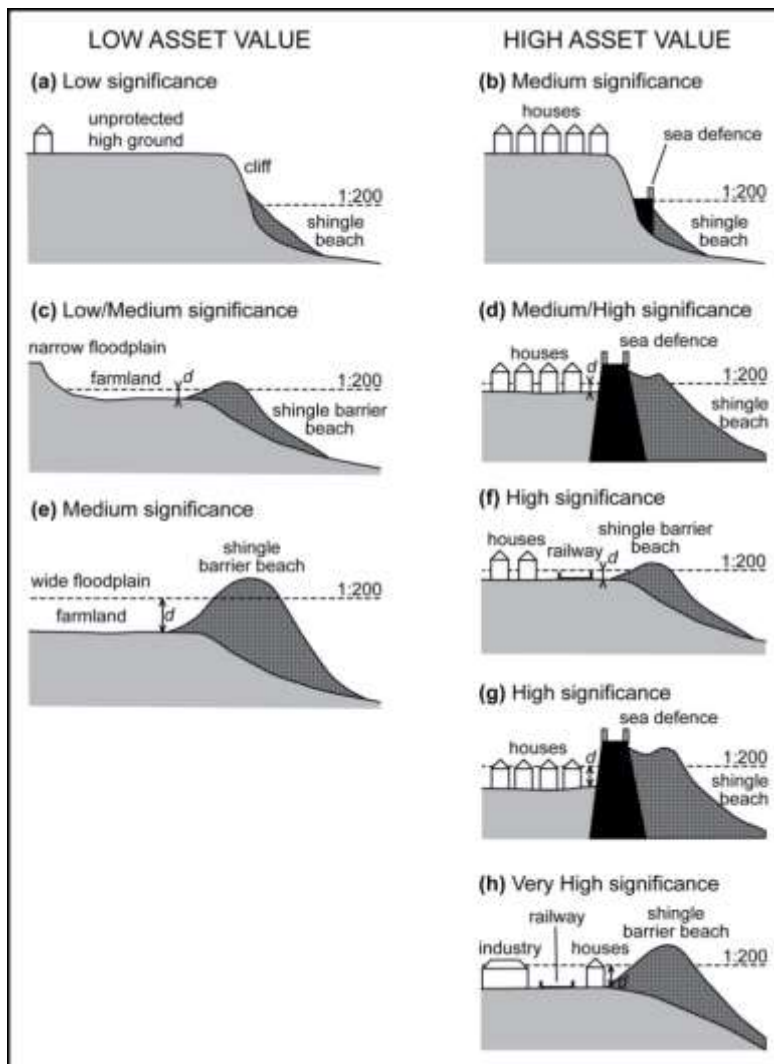

Figure 37 Schematic diagram illustrating different levels of FCERM significance of shingle features

Figure 38 Narrow shingle ridge fronting single storey housing, Aberaeron

Figure 39 High value assets inland of the shingle beach at Pensarn, North Wales coast: from left to right are the A55 trunk road, the Chester to Holyhead railway line and a caravan park access road

7.2. Potential benefits and problems associated with shingle

There are a number of potential benefits and potential problems relating to the FCERM significance of shingle beaches and shingle structures which operate on different time-scales:

Potential benefits:

- a shingle beach, berm or ridge acts to dissipate the energy of waves acting on a coastal defence behind, reducing the standard of defence necessary and prolonging operational life; reduction in the volume of protective shingle can increase risk of wave overtopping, and leave defences exposed and with a reduced residual life
- a relatively high shingle barrier ridge acts to prevent, or reduce, flooding of assets behind arising from wave overtopping and surge tides; if the barrier crest is lowered for any reason, or falls relative to tidal levels and wave run-up due to sea level rise, the effectiveness of the barrier as a coastal flood defence is reduced
- a shingle barrier spit acts to reduce wave penetration into an estuary or lagoon behind; if the spit is lowered, shortened or breached this protective benefit is reduced

Potential problems:

- as with all beaches, there is a risk of landward shingle encroachment during storms onto near-coastal assets, including roads, railway lines, property, and important ecological assets; this risk is likely to increase as sea level rises and barriers move landward by rollover
- there is a risk of blockage of land drainage outlets (streams and culverts) by longshore drifted shingle; this risk is greatest on sections of relatively straight open coast dominated by waves which approach the shore obliquely from one dominant direction
- long-term net alongshore movement of shingle may lead to a permanent fall in beach levels at the up-drift ends of shingle barriers if there is no balancing supply of new material, thereby increasing the local flood risk from wave overtopping and potential undermining of defences
- measures taken to reduce or stop longshore drift of shingle and falling beach levels, such as construction of groynes and breakwaters, disrupt regional patterns of sediment transport, causing sediment starvation to beaches down-drift of the structures and creating pressure for further FCERM intervention measures in these areas
- long-term alongshore drift of shingle can result in shoaling of river mouths, harbours and navigation channels, creating a periodic dredging requirement; disposal of dredged shingle in deep water permanently removes sediment from the coastal system and deprives beaches down-drift of supply

- excessive accumulation of shingle in some down-drift locations, and/or exposure of previously buried shingle and cobbles when sand is stripped from a beach by storms, can be perceived negatively by local communities and local authorities who wish to see a sandy beach maintained for recreational purposes and sometimes remove the exposed shingle and cobbles, with negative long-term implications for long-term beach sediment budget and beach levels
- Increased abrasion of sea defences behind beaches of a certain size leading to premature failure (Dornbusch, 2010).

7.3. FCERM significance of shingle in Wales

Of the 403 sites identified in this study, 41 have been assessed as having high or medium FCERM significance (Table 4), based on a combination of morphological parameters and qualitative assessment of human and natural asset value. The morphological parameters include the height, width and lateral extent of a shingle feature, whether or not it acts as a significant barrier to marine flooding or buffer against coastal erosion, the level of the land behind, and the degree to which the barrier acts to reduce wave action and over topping risk around the margins of the back-barrier area. Examples of high value assets which are protected partly or wholly by shingle beaches and/or structures include Caernarvon Airport (Morfa Dinlle), Aberthaw Power Station, the Cambrian Coast railway line at Llanaber and to the east of Criccieth, and hotels, housing and caravan park developments on the North Wales coast between Llandudno and Rhyl. Some shingle features are important in terms of the protection they provide for historical and archaeological monuments. Examples include the Dinas Dinlle Iron Age hillfort, the 5th century St Tanwyg's Church, Llandanwg, and the 18th century Fort Belan at the northern end of Morfa Dinlle. At a number of sites shingle is also important in contributing to the protection of high value ecological features, such as the Cors Fochno raised bog, located behind the Borth – Ynyslas spit complex on the margin of the Dovey estuary, and the Esgair Cemlyn shingle ridge which protects important artificial tern nesting islands within Cemlyn Lagoon.

A further 55 sites have been assessed as having medium or medium/low FCERM significance (Table 5). The nature of this significance varies between sites, but a broad distinction can be made between sites where the importance relates principally to (a) defence against erosion and sea flooding, and (b) prevention of inland flooding associated with rivers, surface water runoff and/or rising groundwater levels.

7.4. FCERM-related shingle management issues in Wales

The main FCERM management issues relating to coastal shingle in Wales at the present time may be summarised as follows:

- maintenance of a sufficiently high, wide shingle barrier to provide adequate protection against marine flooding or erosion(associated either with wave / tidal over-topping and/or barrier breaching, and/or attack on dunes / cliffs to landward)
- maintenance of adequate land drainage to the sea (maintenance of river/ stream outlets and outfalls)

- alongshore drift of shingle leading to blockage of outfalls, navigation channels and harbour entrances
- shingle washover and throw-over onto coastal infrastructure (roads, railway lines, property) damage to shingle structures and vegetated shingle habitats by placement of caravans, heavy pedestrian pressure and vehicular traffic movements (including plant used in FCERM works)
- management of shingle features for FCERM purposes in a manner which does not disrupt regional coastal processes and does not have negative impacts on other shingle feature interests such as vegetation, fauna, geomorphology, landscape quality and visitor appeal.

These magnitudes and relative importance of these management issues are likely to change in the future due to a combination of natural process impacts and management intervention impacts, as summarised diagrammatically in Figure 40.

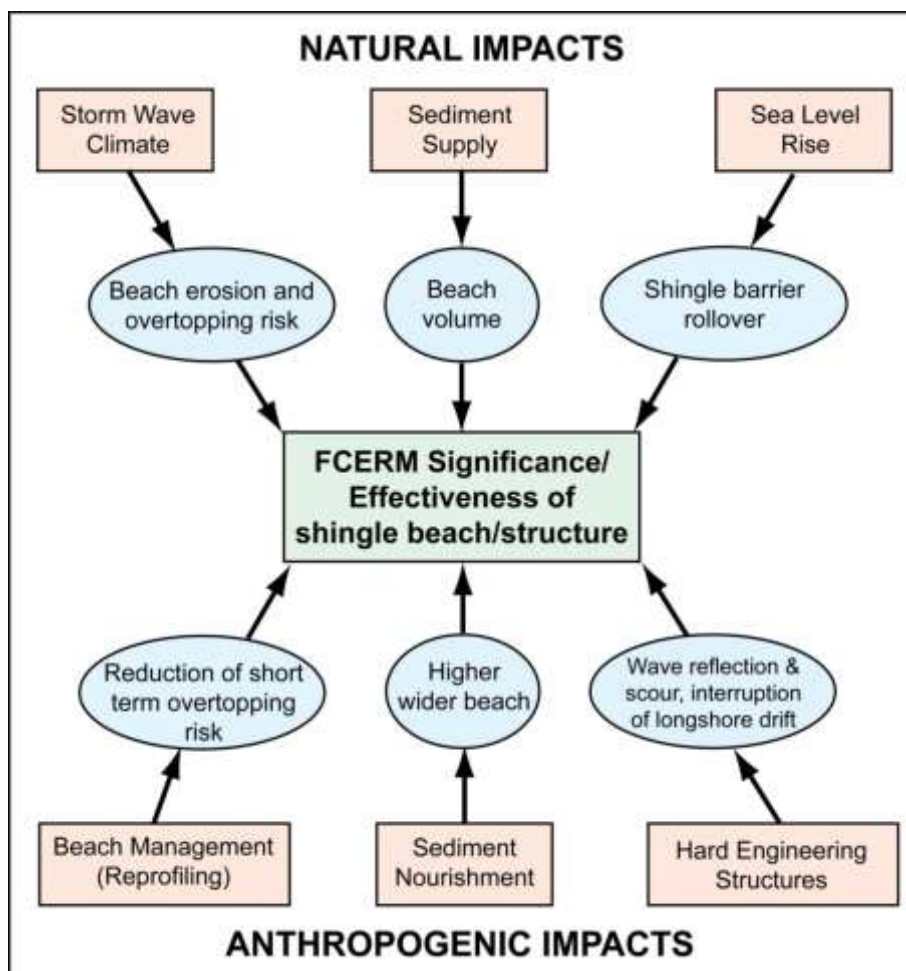

Figure 40 Natural and anthropogenic impact on FCERM significance/effectiveness of shingle beaches and structures

7.5. FCERM and SMP Policy

At the great majority of Welsh sites which have been judged in this study to have high FCERM significance the SMP2 policy in all three epochs is Hold-the-Line, and some form of hard coastal defence is present. As such the shingle features represent only one component of the overall coastal defence. Only at two locations, Ceunant Egryn (Llanaber) and Caernarfon to Plas Menai, is part of the shingle frontage not reinforced by hard structures and the current SMP Policy is either Managed Realignment (MR) or No Active Intervention (NAI). However, at several other sites, including Pebble Beach (Barry), Barmouth to Llanaber, Fairbourne, Craig Ddu to Criccieth, Afon Wen, Traeth Crugan, Morfa Dinlle and Aberarth, the recommended SMP2 policy is change to change from HTL in Epoch 1 to MR or NAI in Epoch 2 and/ or Epoch 3.

At many of the sites judged in this study to have Medium FCERM significance, including Newgale, Aberdovey to Towyn, and Aberdesach, the recommended policy in SMP 2 epoch1 and subsequent epochs is MR but the shingle beach / ridge is still currently maintained, at least in terms of shingle replacement and re-profiling following severe storms. If a policy of MR is progressively adopted in these areas, there is likely to be less maintenance and greater emphasis on managing the roll back of the shingle features, and/or relocating near-coastal assets through 'adaptation'.

8. Shingle beach management methods

8.1. Methods used to manage coastal flooding and erosion risk

Historically, shingle beaches in Wales and other parts of the UK have been managed for FCERM purposes using the following methods, individually or in combination:

(a) beach management without structures:

- proactive and/ or reactive beach scraping (landward movement of shingle) to create and maintain a sufficiently high shingle ridge with crest level above selected joint probability exceedance levels of still water levels and waves
- reactive re-profiling of beach and transfer of over-wash deposits following storms in order to re-build beach ridge crests in the same location and to clear nuisance shingle from roads, promenades and railway lines
- seasonal, annual or aperiodic recycling of shingle from one end of a sediment compartment to another in order maintain adequate beach levels along the entire frontage
- beach and/ or shingle ridge nourishment using imported shingle / cobbles / rock / demolition waste or industrial slag
- placement of sediment on the landward side of a beach / ridge to facilitate rollback (e.g. Dornbusch & Ferguson, 2016)

(b) beach management with structures:

- groynes (timber, rock or concrete) to control alongshore sediment movement
- shore-perpendicular breakwaters (larger than groynes) to control movement of sediment into tidal channels and harbours
- shore-parallel offshore breakwaters to modify wave patterns and encourage beach building and sediment retention behind
- revetments (timber, sheet piling, rock) as structures without beach management:
- rock armour or concrete tetrapods, in front of a shingle berm or shingle ridge
- reinforcement of a shingle ridge to wave action by installing a hard rock 'core'
- immobilization of the surface of a shingle beach or ridge by application of asphalt, cement, pebble / cobble filled gabion mattress, geotextile layers or interlocking concrete blocks
- complete encasement of shingle ridges by concrete walls / promenades

8.1.1. Beach re-profiling

During storms, depending on the coincidence of tidal levels and waves of a given height and period, shingle may be drawn down the beach or transported landwards as wash-over fans. Where shingle is transported landward and impinges on assets such as undefended stretches of railway line or roads (e.g. Figure 41), it may cause disruption to transport services. Current practice in Wales is generally to manage this issue reactively rather than proactively. In

some cases the transgressive shingle is collected and placed back on the beach, with the beach being re-profiled to a typical constant slope of 10 – 20°. However, in instances where the shingle has moved onto a ‘highway’ it is often treated as potentially ‘contaminated’ and removed for use fill, or taken to landfill, thereby resulting in a permanent loss of sediment volume in the local coastal sediment cell.

Figure 41 Section of the Cambrian Coast railway between Barmouth and Llanaber which is protected only by a shingle fringing beach. In the 2013-14 stormy winter transgression of shingle onto the line occurred, and further north parts of the line were washed away

In situations where storms cause shingle to pile up against a promenade (e.g. Figure 42), the excess shingle is often moved away to prevent wave overtopping or ‘throwing’ of shingle onto the promenade. This has the effect of reducing the potential to dissipate storm wave energy at the top of the beach and removal of the shingle from the beach altogether results in a permanent loss of beach sediment volume.

Figure 42 The eastern part of Caswell Bay, Gower. During the 2013-14 winter storms, wave-tossed shingle caused significant damage to the beach front café,; a significant proportion of the remaining shingle was removed from the toe of the promenade by the local authority and placed on the upper beach in a different part of the Bay where it was unlikely to cause further damage (photograph by J. Rewbridge, City and County of Swansea Council)

Re-profiling is often undertaken to create and maintain a pre-determined crest level and/or cross-sectional profile intended to provide a prescribed level of flood protection (e.g. against a 1 in 10, 1 in 30 or 1 in 50 year joint probability of significant over topping). However, such artificial profiles usually are not in equilibrium with storm wave run-up and the beach face and seaward side of the ridge crest often experience erosion, sometimes cutting through the ridge to create a breach (Figure 43). To counter this, design profiles sometimes incorporate a 'sacrificial' sediment berm on the seaward side of the main ridge with a crest level approximately at MHWS or HAT level. However, frequent maintenance is normally required to maintain the design profile which may be unsustainable in the medium to longer term if the beach sediment budget is negative.

Figure 43 Maintained shingle ridge at Llanrhystud, south of Aberystwyth, view looking north

Bull-dozing or other means of moving shingle back up the seaward beach slope, or from washover fans, to rebuild the ridge crest is usually very damaging to pioneer vegetation and may impact adversely on the sediment in-fauna. This is of particular concern where fine gravel and coarse sand deposits seaward of a shingle ridge provide a habitat for rare species such as the amphipod *Pectenogammarus planicrurus* (Webb et al., 2010).

Regular operation of heavy plant on the seaward side of a shingle barrier may also cause compaction and rutting of sub-beach silt and mud deposits, some of which (such as those at Aberdovey – Penllyn, Borth, Rhyl and Abergele) are of intrinsic Quaternary palaeo-environmental and archaeological interest.

Although there are instances where emergency post-storm flood protection works may require some bull-dozing of beach material to prevent further flooding during following high tides, this approach can have significant negative consequences (Rogers et al., 2010) and is unlikely to provide a sustainable means of coastal flood protection in the medium to longer term as sea level continues to rise, without a compensating significant increase in sediment supply.

8.1.2. Shingle recycling

Recycling of shingle from one end of a sediment compartment to the other has been practiced at some locations in Wales, although not on the same scale as at sites in England such as Dungeness and Seaford. The general objective is to maintain a design beach profile across the whole length of a frontage, or to counteract localised low beach levels and defence toe exposure at the up-drift end of local sediment cells, or in the centre of embayments where the upper

beach width is squeezed by coastal defences (Clark & Brooks, 2006). The effectiveness of this approach is partly dependent on local rates of alongshore transport and on the required distance of transport, which affects costs. In England, this approach is usually exempt from marine licencing if carried out within the same sediment cell, but this is not necessarily the case in Wales

8.1.3. Shingle by-passing

This procedure involves artificial movement of shingle in a down-drift direction. It is usually employed to assist the movement of sediment held up by groynes, breakwaters or drainage outfalls. It has been undertaken at Dinas Dinlle, Aber Dysynni and Pontllyfni, amongst many other places. In the case of small rivers and streams, excavation and placement is undertaken using a simple back-hoe digger. In the case of larger streams and tidal channels, or where harbour breakwaters are present, lorries or dumper trucks are often used to transport the sediment to the down-drift side, either along the foreshore at low tide or, if relatively deep water obstacles are present, via longer road routes. However, the latter option is rarely used due to high transport costs and the negative impact of large volumes of road traffic.

8.1.4. Beach replenishment

Shingle beach replenishment has been widely undertaken around the Welsh coast, although schemes have been much smaller than on the coasts of South East England (e.g. Coates et al., 1999; 2001; Moses et al., 2008). Ideally, nourishment is undertaken using rounded pebble or cobble-sized material which is similar in size, or slightly coarser, than the existing beach. The material should also ideally be of a similar lithological composition. However, it is often difficult to find material of a suitable grade and composition within economic transport distance. For this reason, and also because of related cost issues, quarried rock has often been used as a substitute (e.g. Figure 44). While such angular material has some advantages from a FCERM point of view, in that it is relatively cheap if a local source is available, and movement is reduced by angular clast interlocking, it has disadvantages from amenity and nature conservation viewpoints. In moderate to high energy environments rounding of relatively soft rocks such as limestone can occur with 10 – 20 years. For example, at Deganwy and Llandudno West Shore small bounders of angular limestone placed in the early 1990s now show significant rounding and a more natural appearance. As some of the rock clasts break down and become rounded they yield smaller gravel-sized clasts which may be transported considerable distances in an alongshore direction and contribute to the development of shingle and mixed-sand-shingle spits suitable for nesting terns and other birds (Figure 45).

Figure 44 Small boulders of angular limestone placed to create a wave diffusive revetment in front of eroding low dunes, Morfa Conwy

Figure 45 Tern nesting area formed on alongshore drifted shingle derived from dune toe armourstone and rip-rap protection, Gronant, Denbighshire – Flintshire

Local sources of suitable marine shingle, broadly similar in size and composition, may become available from dredging operations with nearby harbours and navigation channels. Dredged mixtures of sand, shingle and even small amounts of mud can be useful for shingle beach nourishment since wave processes rapidly sort the different size grades. Examples where dredged sand and shingle mixtures have been used to nourish shingle beaches and sand dunes include Aberdovey and Holkham's Nose, using

dredge arisings from Aberdovey Harbour and Foryd Harbour, respectively (Figure 46).

Figure 46 Shingle beach backed by dunes at Holkham's Nose formed largely by deposition of shingle and sand dredged from Foryd Harbour within the entrance to the River Clwyd

Where suitable nourishment material is not available from local marine or coastal sources, rounded 'cobble' may be obtainable from inland quarry sources. The Cefn Grianog quarry at Llanllyfni, inland from Porthmadog, has provided an important source of fluvio-glacial rounded boulders, gravel and sand for numerous beach recharge projects in North Wales and West Wales.

8.1.5. Structures to control alongshore sediment movement

8.1.5.1. Groynes

Groynes are shore-normal structures constructed of timber, rock, concrete or rock-filled gabion baskets to restrict the rate of movement of water and sediment in an alongshore direction. On the open coast and in large bays groynes are most commonly constructed as a series to influence sediment movement across a wide frontage (Figure 47), although one or two large rock groynes, including 'fishtail' groynes, may be used to hold a beach over a more limited length of frontage (Rogers et al., 2010; Figure 48 & Figure 49).

Figure 47 An example of effective timber groynes in front of Lanfairfechan promenade

An example of rock groynes at Llanddulas, North Wales, is illustrated in Figure 48 and an example of rock fishtail groyne at Penrhyn, North Wales, is illustrated in Figure 49.

Figure 48 Rock groynes and replenished beach at Llanddulas, North Wales

Figure 49 A fish-tail rock groyne and replenished beach at Penrhyn, North Wales

When correctly designed, groynes can be effective in maintaining a high, relatively wide upper beach which protects any structures behind (e.g. Figure 47), and when groyne bays are sufficiently full with sediment they allow continued alongshore sediment movement. However, where the groynes effectively stop most of the alongshore sediment drift they have the negative effect of starving the downdrift beaches of sediment, leading to falling beach levels and increased risk of overtopping or sea wall collapse in these areas (e.g. Figure 50).

Figure 50 Sediment starved shingle beach down-drift of Aberaeron harbour entrance piers

8.1.5.2. Rock armour revetment

Placement of rock armour is one of the most widely used coast protection measures on account of relative technical simplicity and low cost (in regions such as Wales with local availability of suitable armourstone) compared with schemes which require more sophisticated design and construction methods (HR Wallingford, 2002). Structures range from simple rock revetments with as few as one layer of rocks to complex multi-tiered and size-graded structures (Figure 51). The materials used range from natural rock types such as limestone and granite, recycled waste materials such as crushed concrete, and man-made concrete blocks and tetrapods. A comprehensive guide to available materials, design and construction methods is provided in the Rock Manual (CIRIA, 2007).

Figure 51 Use of rock armour and sheet piling to protect a caravan park and Cambrian Coast Railway, on a former shingle ridge, north of Llanaber, Gwynedd

8.1.5.3. Timber revetment

Shore-parallel revetments can also be built of timber, sheet-piling, old railway track and similar materials. They are usually built in conjunction with groynes, rock armour or other structures. Low revetments (e.g. Figure 52) allow shingle to be 'thrown' over the top by breaking storm waves, but the natural processes of storm over-washing and ridge re-building are severely constrained.

Figure 52 Timber revetment and groynes, Borth and Ynyslas Golf Club frontage, Ceredigion

8.1.5.4. Asphalt aprons

Asphalt aprons are typically used to stabilise the surface of a mobile shingle beach in locations where major changes in beach level could threaten the structural integrity of a sea wall, and/or where shingle 'thrown' over the wall by storm waves poses a hazard to a highway or sea front buildings. An example at Porthcawl, South Wales, is shown in Figure 53.

Figure 53 Stabilization of the upper part of a shingle beach by an asphalt apron, Porthcawl

8.1.5.5. Offshore breakwaters and reefs

Rock can be placed in the intertidal zone to create an emergent offshore breakwater, or below the level of low water to create a submerged offshore reef. In both cases the main objective is to reduce wave energy and flood risk in the lee of the structure. A subsidiary objective and additional benefit is often to encourage sediment accretion behind and to increase the area of recreational beach. The core of the breakwater / reef may be constructed of rubble or dredged mixed sediment with rock placed to form a protective surface layer. One of the first Welsh examples of offshore breakwater was at Rhos on Sea in the early 1980s (Brampton & Smallman, 1985), while one of the most recent schemes involved the construction of a short headland breakwater at Towyn in 2010-11 (Figure 54). As part of this scheme mixed sand and shingle was imported to initiate the development of a tombolo behind the headland, and this has subsequently increased in size through natural sand and shingle accretion. Several smaller emergent breakwaters were constructed as part of the Borth coast protection scheme between 2012 and 2014 (Figure 55). The cost effectiveness of such schemes is influenced to a significant degree by tidal range, construction costs generally being higher in areas of larger tidal range. The effectiveness of breakwaters in building and

maintaining a natural high beach is also dependent on the availability of sediment supply. Where natural sediment supply is low, the combined costs of importing sediment and breakwater construction may make a scheme uneconomic.

Figure 54 Detached emergent breakwater at Towyn, Gwynedd, with a replenished shingle and sand tombolo behind

Figure 55 One of a series of detached rock breakwaters at Borth, Ceredigion

8.1.5.6. Concrete walls and promenades

In many situations where high value assets are exposed to high wave energy, concrete walls revetments and promenades have been built, partly or completely enclosing the shingle structures and/ or sand dunes which were originally present. Promenades were built as part of the development of major seafront holiday resorts in the 19th century, including at Porthcawl, Aberystwyth and Rhyl. Subsequently they have also been constructed to protect residential property, recreational and industrial infrastructure at many other smaller towns and villages, and at locations such as Tanybwllch where a concrete wall and promenade / roadway was built in the mid -1960s to prevent the sea breaking through and potentially diverting the course of the River Ystwyth (Figure 56). A wide variety of seawall and revetment design types and construction methods has been used, and reviews are provided in Thomas & Hall (1992) and McConnell (1998). They are found on the Welsh coast both as stand-alone structures and in combination with groynes, rock armour or offshore breakwaters.

Figure 56 Concrete sea wall and promenade / roadway separating the River Ystwyth from the beach at Tanybwllch, south of Aberystwyth

Concrete sea walls as a ‘permanent backstop’ in the event of beach failure and may be the only viable FCERM option where natural processes do not favour the existence of an adequate protective. However, in effectively fossilizing the shoreline they eliminate or greatly reduce the natural dynamic behaviour of a shingle beach, destroy any inherent geomorphological feature interest, and have major negative impacts on shingle vegetation and fauna.

8.2. Methods for the control of shingle impact on land drainage

There are many hundreds of natural and man-made land drainage outlets around the coast of Wales, ranging from large rivers to small streams and artificial drains. Figure 57 and Figure 58 illustrate a small natural stream outfall on the coast of Ceredigion, where a concrete groyne was been constructed on the up-drift (southern side) to restrict the movement of shingle into the channel. The groyne is now in a state of disrepair and only partially satisfies its design objective. Blockage of the channel with wave deposited shingle, especially at times of low river flow, periodically requires clearance using a mechanical digger. Examples of artificial drainage outfalls on the North Wales coast east of Bangor are shown in Figure 59, Figure 60 and Figure 61. The main outfall from the North Wales Wildlife Trust Spinnies Nature Reserve is located in an area of long-term net shingle accumulation and is frequently blocked by drifting shingle which. The second outfall at the top right of Figure 59 is located in an area of east to west shingle transport. The outfall is sufficiently long that the tidal flat discharges onto the mid-beach, seaward of the main zone of shingle transport, and the landward end of the outfall has a convex form which allows overpassing of drifting shingle.

Figure 57 Natural coastal stream outlet at Llannon on the coast of Ceredigion

Figure 58 Degraded concrete groyne built to limit shingle drift towards the stream outlet shown in Figure 57

Figure 59 The shoreline near the Afon Ogwen, North Wales: the main land drainage outfall from the Spinnies Nature Reserve is sometimes blocked by drifting of shingle. A second outfall (shown in Figure 60 & Figure 61) is located at the top right of the photograph

Figure 60 The seaward end of the small outfall shown at the top right of Figure 59

Figure 61 The landward end of the outfall shown at the top right of Figure 59. The convex form of the landward end of the outfall is conducive to alongshore overpassing of shingle on the upper beach

Management of coastal shingle for inland surface water flood risk management purposes principally involves the following:

- periodic removal of shingle accumulations from river and stream outlets, tidal flaps and outfalls, most commonly excavated using a back-hoe digger and dumper trucks or lorries used to place it on the down-drift side of the drainage outlet

- removal of areas of excess shingle blocking an outlet and placement above the level of tide and wave influence
- construction of groynes, sheet piling walls or gabion walls on the up-drift side of a drainage outlet to intercept alongshore sediment drift
- construction of training walls or piers on both sides of a drainage channel; this has normally been done in areas where seasonal or inter-annual alongshore drift reversals take place, or where navigation into a larger river or harbour needs to be maintained, as for example at the entrance to the River Aeron
- use of barge-mounted excavators or cutter suction dredgers to remove drifted shingle from larger drainage and navigation channels (see Dysynni case study below).

9. Case Studies

As stated in Section 1, four case studies where FCERM interventions are applied have been selected to illustrate some of the issues and opportunities for best practice future management in more detail:

- Dinas Dinlle and Morfa Dinlle – the impact of hard engineering structures on shingle transport and maintained shingle bank flood defences down-drift
- Newgale – the challenges posed by shingle ridge roll-back towards significant coastal infrastructure, requiring consideration of asset relocation and habitat creation through coastal adaptation
- Aber Dysynni – the effect of alongshore drift of shingle on maintenance of land drainage and tidal exchange in a significant estuary (the Dysynni), historically controlled by construction of a terminal groyne, training walls and more recently by dredging and sediment by-passing
- Aberdesach to Dinas Dinlle – where a combination of alongshore drift and barrier rollover presents long term challenges for the maintenance of land drainage and traditional agricultural practices in the coastal plain, but also offers opportunities for the re-creation of dynamic coastal landforms and a range of coastal habitats.

9.1. Case Study 1: Dinas Dinlle and Morfa Dinlle

9.1.1. 'Knock-on' down-drift effects of hard shore defences

At Dinas Dinlle, Gwynedd (see Figure 1 for location), the sand and shingle shoreline has experienced erosion for at least the last 150 years, leading to erosion of The Mound on which an Iron Age hillfort is situated, and creating both an erosion and a coastal flood risk for the village. North of the village is an artificially maintained shingle ridge which provides flood protection for a low lying area of marshland and shingle which forms the southern part of the Morfa Dinlle peninsula, and on which Caernarfon airport is located (Figure 62).

Figure 62 View across the northern part of the Dinas Dinlle frontage, looking towards Morfa Dinlle and the Menai Strait. Note the build-up of shingle, some vegetated, on the southern side of the fishtail groyne and erosion of the shingle bank flood defence on the down-drift side of the groyne

The frontage was badly affected by storms in February 1990, following which several management options studies were undertaken. The final scheme included construction of a rock bastion across the upper part of the foreshore at the southern end of the village, a longer fishtail groyne at the northern end of the village frontage, and slight managed realignment of the artificially maintained shingle bank to the north of the fishtail groyne (Shoreline Management Partnership, 1993; Figure 63). The objectives of the scheme were to reduce, but not entirely stop, the rate of alongshore transport of shingle and sand along the upper beach, to encourage trapping of sediment and increase in upper beach levels in front of the mound and between the groyne in front of Dinas Dinlle village, and provision of flood protection to the road and land leading up to Carnarvon on airport.

Between completion of the scheme in 1994 and 2011 significant net gain of sediment occurred on the up-drift side of the rock bastion and between the rock groyne, with excess accumulation against the landward end of the fish-tail groyne (Pye & Blott, 2011; Figure 62). In order to maintain the northward drift of sediment, Gwynedd Council undertook periodic movement of predominantly shingle across both the southern rock bastion and the fishtail groyne until 2006, when the practice was abandoned. The effect of building

these structures was to starve the beach immediately to the north of the main fishtail groyne of sediment, leading to wave erosion of the sea defence bank behind the beach. The beach in this area was reinforced with imported quarry rock in 1995 and 2005, but erosion has continued (Figure 64). Two more recent assessments of the future management options for this area concluded that, if the crest levels of the fishtail groyne and rock bastion are not lowered to allow greater sediment overpassing, the shoreline to the north of the fishtail groyne will eventually form a shallow zeta-form bay, and that the existing sea defence bank should be realigned accordingly to maintain adequate protection for the coast road behind (Pye & Blott, 2011; Royal HaskoningDHV, 2013).

Between 2013 and 2015 a 200 m long section of the shingle bank north of the village experienced further erosion and localised over-washing, such that the bank no longer provides the level of design protection (Figure 65). Immediately to the north of this area, there has been some gain of sediment on the upper beach fed by erosion immediately to the south, and the ridge has increased slightly in width, forming a subdued projection of the shoreline. However, further to the north again, along the Carnarvon airport frontage, where it has so far been possible to maintain the shingle ridge with a design crest level of 6.0 m OD, monitoring suggests that the beach and seaward face of the bank are coming under increasing pressure.

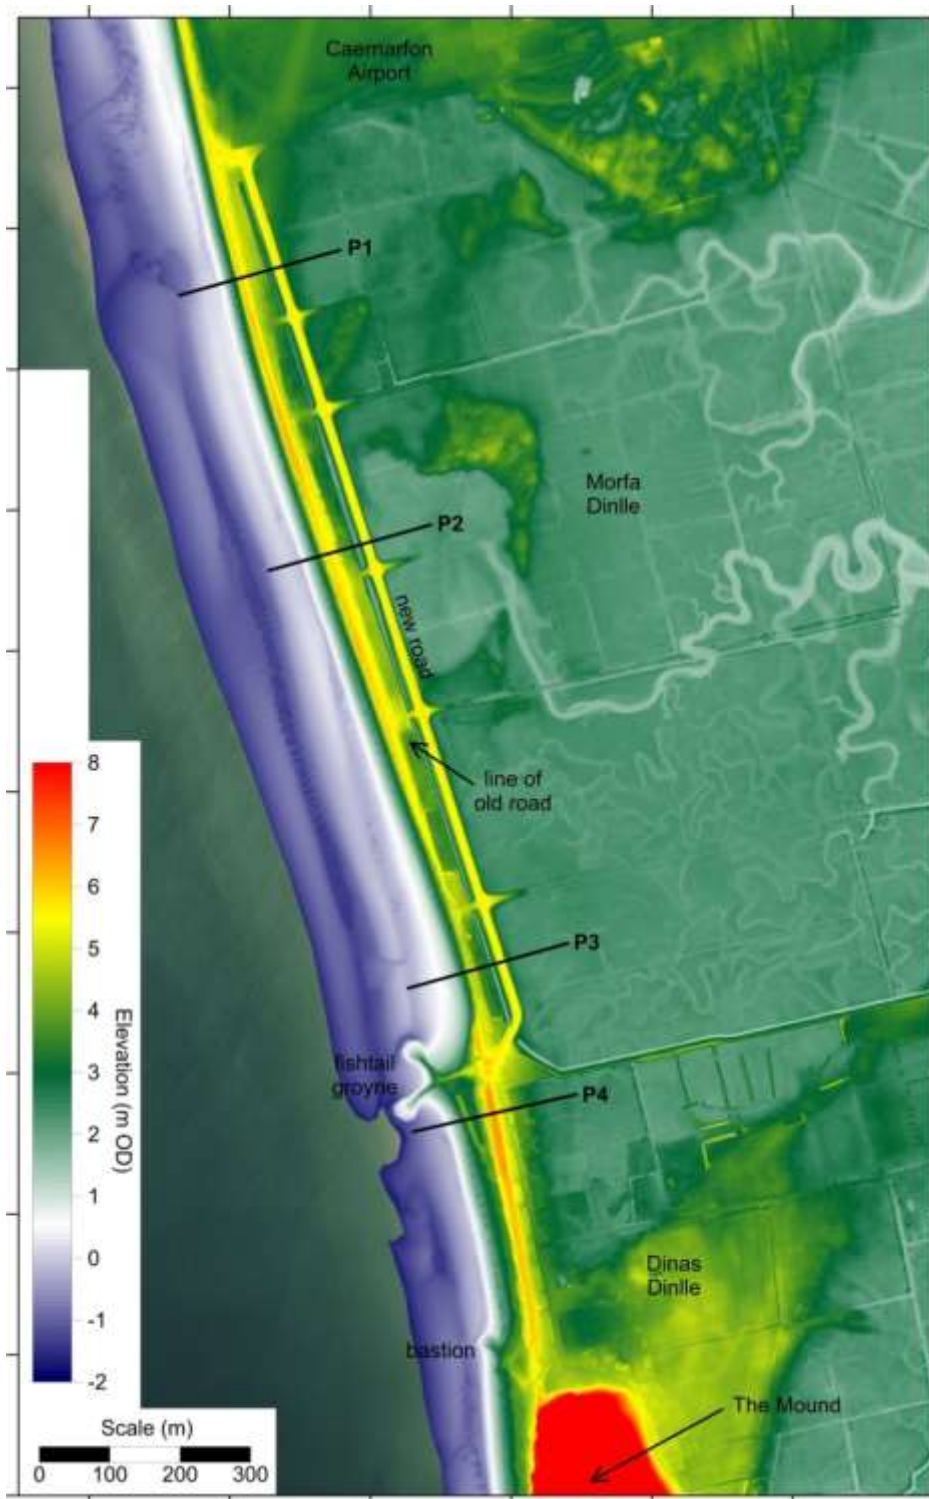

Figure 63 LiDAR digital terrain model of the Dinas Dinlle to Caernarfon airport frontage, flown 4th February 2015, showing hard defence structures built in the 1990s and the shingle bank to the north which is maintained by NRW as a flood defence but which has experienced significant erosion at its southern end, immediately to the north of the fishtail groyne

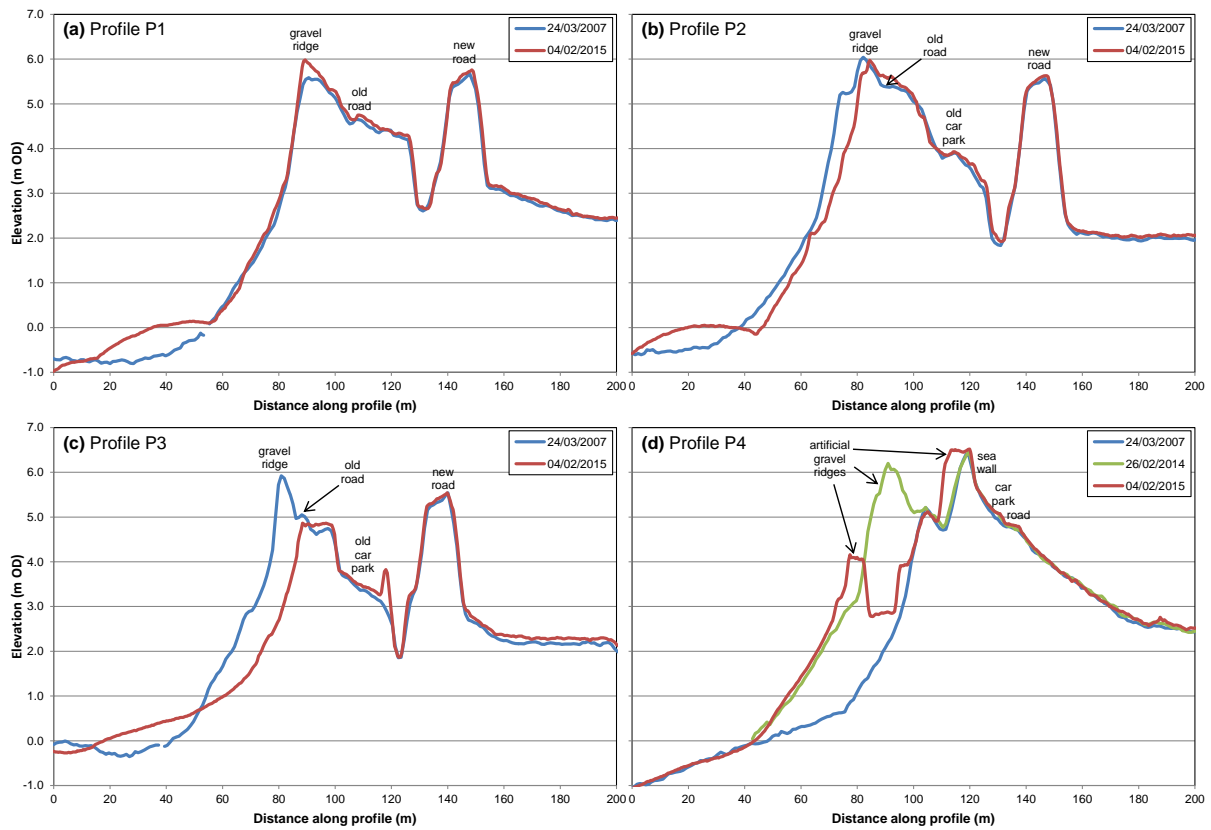

Figure 64 Comparison of cross-shore profiles P1-P4 taken from LiDAR surveys in 2007, 2014 & 2015

Figure 65 LiDAR digital terrain model enlargement of the area north of the fishtail groyne, flown 04/02/2015

This case provides a clear example of the ‘knock-on’ effects of hard defence structures on adjoining sections of shore and coastal flood defences. Although the hard engineering structures have been successful in providing a higher standard of coastal flood protection for Dinas Dinlle in the short term, they made the task of maintaining the flood bank to the north more difficult.

9.1.2. Likely effects of accelerated sea level rise

Over the next 20 to 50 years the pressure on the beach and shingle ridge to move landward is likely to increase, and maintenance of the flood defence bank on its present alignment will become unsustainable. In the short term

(next 20 years) it may suffice to allow a 'stable' shallow bay to develop at the southern end of the bank, allowing shingle to be periodically over-washed into the low ground area between the outer bank and the new road. However, in the medium to longer term it is likely to be impractical to maintain the design profile along much of the outer bank, with the possible exception of the northern end. Even if the present rate of sea level rise (c. 2mm/ yr), this will mean an increase in mean sea level of 10 cm over the next 50 years. The evidence from historical tide gauge records for stations such as Holyhead and Milford Haven suggests that spring tide high water levels are likely to increase more rapidly than mean sea level; this combined with projected greater frequency of severe storms in a warmer world, will act to driving the shoreline in a landwards direction. Although sea level rise and greater storminess may also enhance the rate of soft cliff erosion to the south of Dinas Dinlle, it is unlikely that this will produce sufficient supply of new shingle to offset the effect of rising sea level along the entire Morfa Dinlle shoreline.

9.1.3. A suggested 'good practice' way forward

Hardening of the entire seaward side of the outer bank with rock armour or other structures would be undesirable on environmental and aesthetic grounds and in any case is unlikely to be economically justifiable. The presently maintained shingle bank should therefore be allowed to adjust to a more natural profile and move landward in equilibrium with rising sea level. This increased dynamism would bring environmental benefits in the form of a variety of bare and vegetated shingle habitats, together with small saline / brackish lagoons and transitional habitats. However, if such a policy is adopted the new road embankment would act as the main flood defence and would need to be strengthened, raised or moved further landward if all-weather road access to the airport and Fort Belan at the northern end of Morfa Dinlle is to be maintained. An alternative, potentially lower cost approach would be to accept that access along the road will be occasionally disrupted as a result of storms, and to convert the road to a more adaptable design which can be easily reinstated if sections are washed out.

9.2. Case Study 2: Newgale, Pembrokeshire

9.2.1. Barrier rollover and shingle 'squeeze'

The Newgale shingle ridge, located in the northern part of St. Bride's Bay, Pembrokeshire (Figure 1), consists of two sections of barrier beach on either side of a short section of fringing beach around an outcrop of rock at Sibbernock Point (Figure 66). The ridge is composed of shingle derived both from local rocks around the margin of the Bay and from reworked glacial sediments (Harrison, 1965). The beach is almost swash-aligned although in most years there is a slight net sediment drift towards the north owing to the dominant effects of offshore southwesterly waves. The southern section of barrier beach acts to reduce coastal flooding of the seaward part of the Bathesland Water valley. The second, longer, section provides flood protection

for the lower parts of the Brandy Brook valley, the Newgale Sands southern car park, a camping ground, two properties and the main A487 coast road (Figure 67). The Brook drains to the sea through a narrow outlet at the northern extremity of the barrier and is periodically blocked by shingle; this is cleared by NRW to prevent fluvial flooding in the valley, with the shingle placed back on the adjoining ridge (Figure 68).

The shingle barrier ridge itself is currently maintained by Pembrokeshire County Council (PCC) as a coastal flood defence. The shingle beach and barriers are located with the Pembrokeshire National Park but not within a designated SSSI or SAC. The crest level of the barrier is intended to meet a 1 in 5 year event standard, but this is increasingly difficult to achieve. During the stormy winter of 2013-14 the barrier crest was overtopped and lowered by up to 2 m, and landward spread of shingle resulted in extended closure of the A487 road link to Newgale village and disruption to neighbouring businesses. When the road is closed, traffic has to follow a 6.2 km inland diversion using single track rural roads.

A comparison of LIDAR surveys in 2006 and late March 2014 demonstrates that the shingle ridge crest moved landwards slightly over this period (Figure 69), and has also lost elevation at its northern end due partly to shingle being washed into the Brandy Brook channel or spread onto the road from where it has been taken off-site. Most of the landward movement of the crest occurred during the stormy winters of 2006-7 and 2013-14; analysis of historical maps and aerial photographs has indicated that this is part of a longer term trend by which the barrier is experiencing 'rollover'. However, owing to the presence of the fixed roadway, the active upper beach and ridge crest cannot migrate freely and is being 'squeezed'. This trend is likely to continue, and may be enhanced, by projected increases in sea level over the next 100 years.

9.2.2. Good practice assessment of management options

The West of Wales Shoreline Management Plan (RHDHV 2011) concluded that as sea level rises it will be increasingly difficult to maintain the Newgale barrier in its present form, and a separate report to PCC (RHDHV, 2014) concluded in the medium to longer term it will be necessary to allow the shoreline to roll back and to realign the A487. Following public consultation, a Final version of an Adaptation Plan was published by PCC in May 2015. A further report by RHDHV (2016) anticipated that under a 'Do Nothing' scenario the barrier would retreat by 7.5 m in 20 years, 12.5 m in 50 years and by 25 to 47 m in 120 years. A number of short term 'Do Minimum' options to maintain the road have been considered, including rebuilding the shingle bank in advance of a storm, raising the crest of the bank to prevent overtopping, and reinforcing the core of the bank, but none are considered by the consultants to provide a sustainable or effective solution. Reasons for this include the fact that sea level is rising, the supply of new shingle to the barrier is very restricted, the natural response of the barrier to both storms and sea level rise is for the seaward face to be eroded and the crest to move landward. Creation of a hard core, while it might fix the position of the lower part of the barrier, would not prevent lowering and wash-over of the crest. Three long-term options were also assessed by RHDHV, including a sea wall, an embankment with rock revetment, and a short-term gabion solution replaced in the longer term by a rock revetment and concrete wall solution with crest height of about 10.5 m OD. However, it was concluded that with all three options the shingle bank would disappear and upper beach levels would fall, changing the character of the shore and potentially leading to exposure of the toe of the defences. Estimated costs of these options ranged from £12.5M to £19.51M. It was pointed out that none of the options considered would address the problem of potential storm flooding via the Brandy Brook outlet, or as a result of heavy rainfall within the Brandy Brook catchment. The preferred solution identified therefore suggested realignment of the road and eventually to remove all associated infrastructure.

Following further public consultation of options for the road, a Final WelTAG Stage 1 Assessment report was published in July 2017 (Atkins, 2017). An Adaptation Strategy Plan (ASP), published in March 2017 (Atkins & RHDHV 2017), identified the following objectives:

- ensuring connectivity with the rest of Pembrokeshire
- maintaining physical and functional links between the northern and southern edges of Newgale
- maintaining connection to the beach
- maintaining and enhancing the natural environment
- sustaining community well-being and empowering locals to take a lead role in adapting to change
- sustaining of business opportunities
- supporting tourism

The ASP identified potentially significant effects including loss of the existing A487 road over the next 10 - 20 years, movement of shingle towards two

existing businesses (the Duke of Edinburgh Pub and the Surf School, cafe and shop) and into the Newgale campsite which would also be subject to increased flooding from wave overtopping and ponding of water within the valley. However, opportunities associated with these changes are also identified in the ASP, including creation of wet woodland and saline lagoons, opening up of the valley area to provide additional visitor attractions (e.g. for walking, bird watching), and development of additional visitor / business facilities.

The WeITAG Stage 1 Assessment included consideration of landscape designation constraints, habitats and species likely to be affected by each of the four options identified after consultation on the initial assessment by PCC, together with preliminary engineering designs and forecast costs for each (suggested cost range £16M - £28.5M). Based on this assessment, the report recommended that the existing road line should be realigned approximately 60 m inland of the present route, with the road built on a viaduct at a level approximately 3m above the ground. A high level environmental appraisal analysis of likely new habitat development in response to such a strategy was reported by RHDHV (2017). The report considered there is likely to be an increase in both saline and freshwater flooding, due partly to more frequent blocking of the Brandy Brook outlet as the shingle barrier rolls back, but this would provide opportunities for the creation of a range of wet and transitional brackish to freshwater habitats.

This case study provides a good example of the problems created by shingle barrier rollback, which is likely to become more rapid in response to an acceleration in sea level rise, and of best practice options appraisal which has included detailed assessment of background physical process, flood risk management issues, economic impact, and potential environmental costs and benefits. Considerable effort has already been spent on the options appraisal and public consultation, although a final decision on a preferred option will be dependent on the results of further detailed site studies and availability of funding.

9.3. Case Study 3: Aber Dysynni, Gwynedd

9.3.1. Effect of alongshore shingle drift on flushing efficiency of the Dysynni estuary

The Aber Dysynni shingle feature forms a shingle spit extending northwards from Towyn towards the entrance to the Afon Dysynni (Figure 1 and Figure 70). The spit has developed across the mouth of a former large estuary under the influence of strong northerly sediment drift, driven by dominant waves from the southwest. Saltmarsh (Morfa Gwyllt) developed behind the spit but much of this was enclosed by embankments, and the land drained, in the late 19th and early 20th centuries. The Broadwater remains as a residual feature of the original estuary.

Since 1878 most of the shore south towards Tywyn has experienced erosion, supplying large amounts of sediment which has moved north towards the mouth of the Dysynni and around the Tonfannau headland (Figure 70). The spit

has extended northwards, forming a series of abandoned re-curves which have been mined for gravel at various times (Figure 71). This northward movement of shingle continues today, constricting the mouth of the Dysynni, pushing it towards the Tonfanau side, and inhibiting the movement of Dysynni floodwaters towards the sea.

Figure 70 Tywyn to Aber Dysynni 2006 aerial photograph with superimposed 1878 MHW line

Figure 71 Aber Dysynni Lidar DTM based on surveys 2007-2015. Note area of low ground near profiles P1 due to former gravel workings

When the Cambrian Coast railway line was built in the mid-19th century, training walls were constructed to control flow and movement of the main estuarine channel beneath the railway bridge. Later, in the early 20th century, an additional breakwater was built around the northern end of the spit to regulate the movement of shingle into the channel. However, build-up of shingle against the southern side of the structure continues, and incursion into the channel presents an ongoing problem for the maintenance of land drainage.

An embankment was constructed around the northern end of the spit in the mid-20th century to facilitate gravel extraction, and an area of low ground remains between the active shingle ridge and the landward river embankment (Figure 71 & Figure 72). Along the section of the spit centred on Profile 2 shown on Figure 71 the shingle ridge is very narrow and has a maintained crest elevation of approximately 8 m ODN (Figure 72). This ridge provides an important defence for the railway line and a large area of low-lying land behind (Figure 73). The most vulnerable section of the ridge is protected by a relatively narrow zone of rock armour on the seaward face.

The glacial till shoreline at Towyn has been protected by wooden groynes and a concrete promenade for over a century, and in more recent years rock groynes and a headland breakwater have been constructed (Figure 54). This has eliminated the sediment supply provided by cliff erosion in this area and contributed to a sediment deficit on the beaches fronting the southern part of the Aber Dysynni shingle ridge complex. A shallow bay is now forming to the north of the sewage works, placing additional stress on the ridge in this area. The natural recession of the ridge immediately to the north of this point is prevented by rock armour, but beyond the northern limit of the shore protection the ridge has a relatively natural form with storm wash-over fans in several places. The 2006 and 2013-14 aerial photographs (Figure 70 & Figure 74) show the extension of these fans into the area of former gravel workings at the northern of the spit. Diversion of shingle into this area is beneficial in restoring a more natural landscape and also in reducing the amount of material moving alongshore into the mouth of the Dysynni.

9.3.2. Channel maintenance by dredging and shingle bypassing

NRW (and previously Environment Agency Wales) have for many years removed shingle from the southern side of the Dysynni channel and placed it on the northern (Tonfanau side). Areas in which extraction and placement are permitted under the terms of the current Marine Licence are shown on Figure 74. While this practice has a beneficial effect in maintaining a supply of sediment to the beaches north of Tonfanau there is some risk that part of the sediment placed on the north side of the estuary can return to block the channel at times of strong north-westerly wave activity. Placement of the material further down-drift, or higher up the beach, could reduce the risk, but would involve additional transport distance / and cost.

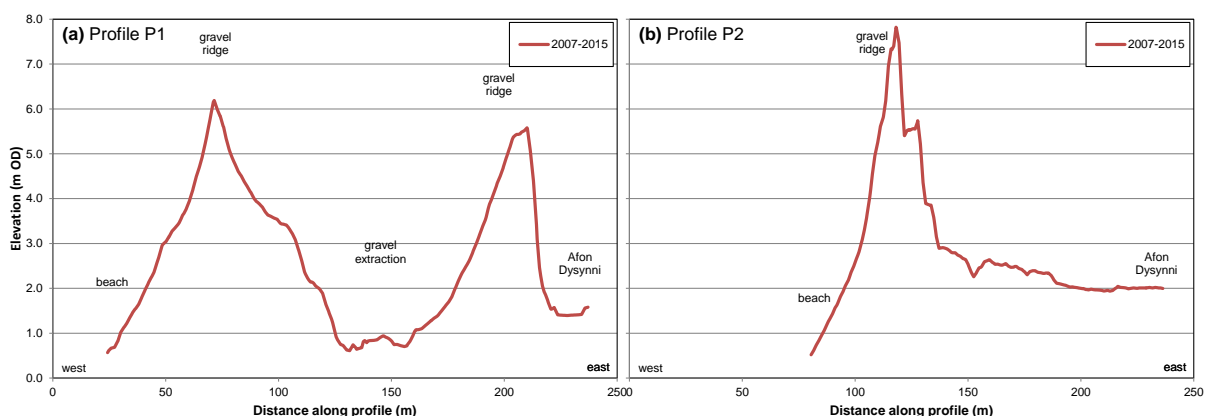

Figure 72 Aber Dysynni: cross sections P1 and P2 across the shingle ridge (extracted from the 2007-15 LiDAR DEM)

Figure 73 Tywyn to Aber Dysynni: areas below the estimated 1 in 200 year storm surge level coloured blue

Figure 74 The northern end of Aber Dysynni spit, showing the locations for which NRW currently hold a Marine Licence to remove and deposit shingle (superimposed on 2013-14 aerial photography)

9.3.3. Future management options

This case study provides a good example of the challenges posed by strong alongshore drift of shingle for the maintenance of large-scale land drainage. The present management strategy of shingle by-passing of the Dysynni entrance has reduced, but not eliminated, the problem of constriction of the entrance, and has maintained continuity of sediment transport towards the north of Tonfanau. At the present time the low water channel of the Dysynni lies very close to the Tonfanau shore and there is limited space to place additional material. An option to cut a new channel through the spit, south of the present low water channel outlet and north of the existing terminal breakwater / groyne, is under consideration. However, while this option would relieve the pressure for northward movement and infilling of the low water channel, in itself it would not provide a complete solution. The issue of beach lowering and narrowing close to the sewage works is likely to continue, and may accelerate with sea level rise, releasing more sediment which mostly would be transported towards the new cut. Other, complementary intervention

options should therefore also be considered, including shallow excavations to further encourage movement of wash-over shingle into the former gravel extraction areas, and transport of some shingle back up-drift to the area north of the sewage works (shingle recycling).

9.4. Case Study 4: Pontllyfyni to Dinas Dinlle, Gwynedd

9.4.1. Combined problems of land drainage, barrier rollover and alongshore drift

The Gwynedd coast between Aberdesach and Dinas Dinlle (Figure 1 and Figure 75) provides a good example where drifting shingle regularly causes a problem for small-scale land drainage outlets from the adjoining coastal plain. There are six main land drainage outlets in this area, the largest being the artificial cut of the Afon Llyfni. This section of coast is fringed by a series of relatively narrow shingle barrier beaches which are backed by quite extensive areas which lie below the estimated 1 in 200 year marine still water level (Figure 76). Consequently there is a risk of marine flooding as well as land-based flooding arising from blockage of the drainage outlets. Artificial banks and ridges of re-profiled shingle have been created by local landowners and/or EAW/ NRW at various times, but due to continuing shoreline recession these are regularly breached or over topped and have required periodic landward realignment. The arrangement of drainage ditches on the landward side of the shingle has also required adjustment in several places as the shingle has migrated landward and filled some of the older ditches (Figure 77). Blockage of the landward side of outfall pipes which pass under the shingle ridge is often more of a problem than blockage on the seaward side.

The Pontllyfyni part of the frontage is characterized by a series of connected washover lobes which were reactivated, if not entirely formed, during the February 1990 storms and again in the 2013-14 winter (Figure 78 & Figure 79). These now provide interesting dynamic geomorphological features with a range of vegetation successional stages evident.

9.4.2. Likely effects of future sea level rise

The supply of new sediment from the south is currently limited, but rates of alongshore drift can be high during periods of strong south-westerly wave action. As a result, foreshore levels in the Pontllyfyni area are likely to continue to drop and there will be increased pressure for the shingle ridge to rollover landwards, probably decreasing in sediment volume and crest height as it does so. In the medium to longer term, as sea level rises, the requirement for intervention works to maintain high shingle flood banks, and to clear drainage ditches and outfalls, will increase and may become unsustainable given financial constraints and the relatively low asset value which is protected.

9.4.3. Options for future management

Allowing the coast to adapt naturally would result in some landward movement of the shoreline and would require periodic adjustments to the land drainage system, including re-design of some drainage ditches and outfalls. This could include re-design of the drainage system so that discharge to the sea is through fewer but larger outfalls which have longer pipe sections (extended both landward and seaward). This would require one or more capital schemes but could bring long-term savings in terms of maintenance. Such a change in management approach would also allow the shoreline line shingle features to adopt a more natural, dynamic form (Figure 80 **Error! Reference source not found.**) and create a range of shingle habitats, including small saline lagoons, which could of vegetation and wider ecological value.

Figure 75 Location of land drainage outlets on the coast between Aberdesach and Dinas Dinlle, Gwynedd. Also shown are the positions of MHW in 1878 and 2006

10. Conclusions and recommendations relating to shingle management best practice

10.1. Artificial shingle banks and replacement with more 'natural' profiles

Shingle beaches can be efficient in dissipating wave energy and shingle storm beach ridges act as barriers to overtopping during all but the highest tides; as such they represent effective contributors to coastal flood defence in Wales, and elsewhere. A total of 42 shingle sites on the Welsh coast have been identified as having high or medium FCERM significance. However, unlike sand dunes which can grow vertically to several tens of metres above storm tide level, no natural shingle ridge can provide complete protection against overtopping since the crest height is limited by run-up under swell-wave conditions, and crests may be lowered by overtopping, cliffing and / or breaching during severe storms. For this reason there is a long history in the UK of artificial profiling shingle ridges to create an artificial embankment which is usually flat-topped with straight, relatively steep sides, sometimes with a 'sacrificial' berm mid-way down the seaward slope. However, such features are not in equilibrium with incident waves and can be rapidly modified by cliffing when subject to high waves and tides. Owing to the high crest level, the sediment eroded from the beach face is likely to be moved offshore or alongshore, possibly being lost from the local sediment cell altogether, and resulting in progressive loss of sediment volume from the embankment (Figure 81a).

(a) Artificially Maintained Shingle Ridge

(b) Non-Maintained Shingle Ridge

Figure 81 Schematic evolutionary scenarios for (a) an artificially maintained shingle ridge, and (b) a non-maintained shingle ridge

As part of good practice, the creation of such artificial banks should be avoided wherever possible, since regular intervention is required to maintain the design profile, and this may become unsustainable in areas where the beach sediment budget is negative. Such intervention measures also destroy the natural geomorphological features interest and have a serious negative impact on shingle vegetation and other ecological interests.

When the process of maintaining an artificial embankment profile is abandoned, a process of natural adjustment will result by which the ridge crest moves landward slightly and adopts a more natural flatter, convex-concave profile (Figure 81b). This process has been well-documented following the cessation of embankment crest maintenance at sites in Norfolk, Suffolk and elsewhere. Since over-washing is a significant process in the scenario illustrated by Figure 81b, less sediment is lost offshore and alongshore and the ridge is more likely to retain near-constant volume as it moves landwards.

The management options available for managed and unmanaged shingle banks and ridges, together with indicative FCERM effectiveness, cost, ecological impact, geomorphological / landscape impact and recreational impact, are summarised in Table 6, based on evidence from previous guidance, publically available assessment reports and the authors' own experience. Although installation of hard defenced offers the highest level of FCERM effectiveness, this option also involves the highest cost and has the greatest negative impact. Repeated re-profiling can have medium to high short-term FCERM effectiveness but low long-term effectiveness, while having high environmental impact throughout. Beach nourishment may offer the best overall compromise by allowing a wide beach and relatively high multiple ridge or platform to develop, although costs could vary widely depending on location, availability of suitable sediment, requirement for beach control structures, and requirements for repeat re-nourishment.

Table 6 Management options for shingle ridges and embankments without existing hard defences (minus signs indicate negative impact, plus signs indicate positive impact)

Option	FCERM Effectiveness and Sustainability	Cost	Ecological Impact	Geomorphological/ Landscape Impact	Recreational Impact
Repeated re-profiling after storms – may be unsustainable if net trend is for loss of sand and/or shingle	L	M	H (-)	H (-)	H (-)
Hard protection (rock armour, tetrapods)	H	H	H (-)	H (-)	H (-)
Beach nourishment (with or without beach control structures)	M	M	M (+)	M (+)	H (+)
Do nothing and allow rollback; adapt use of hinterland and/or provide hard protection around particular assets	L	L-M	M (+)	H (+)	M (N)

10.2. Provision of secondary flood defences and resilience measures

Where immovable assets of sufficiently high value are located behind a shingle ridge to warrant creation of an artificial flood bank, good practice should include creation of a concave-convex design profile which approximates a natural profile as closely as possible. If insufficient sediment is available locally to create such a profile of required crest height, a lower crest height and increased overtopping risk should be accepted, secondary flood protection measures put in place around the assets where they take the form of individual buildings or groups of buildings. Owners of the assets should also be encouraged to install suitable resilience features to allow the assets to withstand occasional flooding.

10.3. Hard defences vs coastal adaptation

Historically, significant lengths of shingle shoreline in Wales have been 'hardened' to protect inappropriately sited urban development and other assets using a range of engineering structures such as groynes, revetments, sea walls and shore-detached breakwaters. In some places this has totally destroyed the nature character of the shoreline and any associated ecological interest features. Hardening of one length of shoreline almost inevitably has a negative effect on sediment supply to adjacent areas down-drift, leading to progressive extension of the defence structures in a down-drift direction (as discussed in relation to the Dinas Dinlle case study in this report). Further lateral extension of defences and hardening of the shoreline should be avoided, wherever possible, since the process is self-perpetuating.

Given that sea level is now rising, and the rate of rise is projected to accelerate in response to global climate change, the natural response of many shingle beaches and storm beach ridge structures would be to rise in elevation and move landwards by 'rollover'. Unfortunately, there are many places where this is now difficult, if not impossible, and shingle features are being 'squeezed' because buildings, roads, railways and other assets have been built on, or very close to, the shore. Depending on the value of the assets and the relative costs of defence improvements, an adaptive strategy of asset re-location and habitat re-creation may be the most cost-effective and environmentally beneficial option (e.g. as discussed in relation to the Newgale case study). As part of strategic good practice, opportunities should be sought to remove, or modify, existing defences, especially where they serve no useful purpose in their present form, in order to restore the functioning of natural processes and natural habitats (cf. Environment Agency, 2012).

10.4. Incorporation of beach creation and maintenance into scheme design

In locations where the restrictions of geography and value of assets make a managed realignment / adaptation approach impractical, a viable business case may be made to upgrade or replace existing hard defences. In such

situations, management of shingle beaches still has an important part to play since, under a best case scenario with hard defences present (Figure 82a). The presence of a wide, high beach provides a first line of additional defence to any hard structure behind, and also offers opportunity to provide useful recreational space and areas where shingle vegetation can develop.

Where a wide, high beach is not present, a non-ideal scenario with hard defences present will arise. Wave reflection, toe scour, wave splash overtopping and shingle throw will all represent problems which will need to be managed (Figure 82b). The intervention options available in such a situation, together with indicative FCERM effectiveness, cost, ecological impact, geomorphological / landscape impact and recreational impact, are summarised in Table 7. The greatest FCERM effectiveness is delivered by the hard engineering options, but once again these are likely to have the highest cost and greatest environmental impact. Beach nourishment may provide a relatively lower cost option with smaller negative environmental impacts, but the FCERM benefits are likely to be lower and shorter lived. Where rates of new sediment supply are insufficient to allow maintenance of an equilibrium beach morphology in the face of sea level rise, the beach will no longer function as an effective sea defence and will need to be completely replaced by hard defences in the longer term (Dornbusch, 2017).

Figure 82 Schematic representation of evolutionary scenarios for situations with hard defences and (a) a wide, high beach present, and (b) only a narrow, low beach present

Table 7 Management options, FCERM effectiveness, relative cost and relative environmental impacts for a situation with hard defences and a low, narrow beach

Option	FCERM Effectiveness and Sustainability	Cost	Ecological Impact	Geomorphological/Landscape Impact	Recreational Impact
Shingle or sand/shingle nourishment (with or without beach control station)	M-H	M-H	M (+)	M (+)	H (+)
Rock armour	H	H	H (-)	H (-)	H (-)
Offshore Breakwaters	H	H	M (N)	H (-)	M (N)
Build bigger/better wall	H	H	H (-)	H (-)	H (-)
Remove defence and allow roll back	L	M-H	M-H (+)	M-H (+)	M-H (+)

10.5. Best practice associated with shingle beach management schemes

As part of general best practice, any shingle beach management scheme should seek to reduce the stress on, and increase the resilience of, shingle habitats, prevent loss, damage or fragmentation of habitats and species, and seek to secure the value and benefits of the range of ecosystem services provided.

Surface disturbance should be kept to a minimum in order to allow shingle vegetation to develop; infrequent re-profiling of the upper parts of beaches and beach ridges encourages stability and the build-up of interstitial fine sediment required for shingle vegetation development.

Trampling disturbance is a particular problem for strandline pioneer communities and for bryophytes found on older, stable shingle surfaces (Scott & Randall, 1976, Randall, 1977b). Vehicle movements, including plant used in FCERM operations, can be a major problem. To facilitate continued development and survival of these communities, vehicular and pedestrian access needs to be restricted to guided routes during and after scheme completion.

Regular monitoring of beach levels should be undertaken to anticipate problems and intervention requirements before they become major issues which require large-scale emergency works; i.e. proactive intervention is far better than reactive intervention

Ecological surveys should be undertaken prior to any works to establish the extent and importance of habitats and species present, and intervention work at critical times of the year (e.g. plant flowering / seeding and bird nesting times) should be avoided.

An adequate geomorphological baseline study should be undertaken to inform the development of a beach management plan (e.g. Pye & Blott, 2017; AECOM 2017c), with repeat assessments at intervals of 5 years informed by annual or bi-annual site inspections and analysis of monitoring data.

Where extensive FCERM schemes are undertaken, appropriate shingle restoration or enhancement measures should be incorporated in the final stages to encourage the establishment / re-establishment of shingle vegetation and associated invertebrate fauna (e.g. Walmsley, 1995; Walmsley & Davy, 1997a,b,c, 2001). This may involve local introduction of surface fine sediment, seeding, planting, fencing to reduce trampling in the short term, based on the best available professional advice.

Wherever possible, FCERM interventions should seek to replicate natural beach profiles as closely as possible, with the possible addition of a wider backshore 'platform' if beach nourishment is being undertaken. Also wherever possible, the sediment type and grading should match the naturally existing material, although in some instances it may be desirable from a scheme performance point of view to use material which is coarser than the pre-existing sediment. Finer sediment should not be used unless an intention of the scheme is to encourage the development of dunes behind or on top of the shingle ridge at the back of the beach.

10.6. Requirements for geomorphological baseline assessment and subsequent monitoring

The geomorphological baseline assessment should include at least the following elements:

- review of background literature and unpublished reports
- examination of historical maps, charts, aerial photography and LIDAR survey data, ideally within a GIS framework
- analysis of previous ground topographic survey and sediment survey data
- assessment of coastal processes data (predicted and recorded tidal levels, predicted and recorded storm surge levels, tidal currents, winds, waves, sediment transport)
- site walkover survey with photographic record of principal geomorphological features, evidence of erosion / accretion, sediment types and distribution, presence of structures, presence of features of ecological interest

If no recent ground survey, aerial LIDAR survey, aerial photogrammetric survey or sediment data are available, new surveys should be commissioned prior to aid the assessment, and prior to any FCERM intervention works being undertaken. For ground surveys, quad-bike mounted RTK GPS surveys are preferable to line surveys since they provide better three-dimensional information, but if resources are limited, or access / use of quad bikes is restricted, shore-normal line surveys should be undertaken at 50 m intervals along the shore, extending over the crest of the shingle ridge to the landwards slope or artificial defence behind.

If no recent aerial photography is available, a new survey should be commissioned. For relatively small areas, an unmanned aerial vehicle (UAV or 'drone') survey undertaken on a low spring tide may be most cost-effective. An interpretative geomorphological map should be prepared on the basis of the aerial photography / LIDAR imagery and the ground walk-over survey.

If no recent sediment data are available, a sampling survey should be undertaken on a low spring tide. Sampling should be undertaken along at least three shore-normal transects located towards each end and the middle of the beach. For long sections of shore, more transects may be required. Samples should be taken from the shingle ridge crest, upper beach slope, mid foreshore and lower foreshore on each transect. All sampling locations should be photographed immediately prior to sampling.

Samples should be sufficiently large to give a representative size distribution: for sandy and muddy mid- and lower beach sediments a sample size of 500g (or 500 ml pot) is usually sufficient, for coarse and fine gravel mixtures 1kg (or 1 litre pot) is sufficient, but for upper beach and shingle ridge sediments which are often dominated by medium and coarse gravel larger sample sizes of up to 25 kg may be required. Where possible, samples should be taken to a suitably equipped laboratory and analysed by dry sieving at 'half-phi' intervals. If taken from a sensitive location the sample material should be returned to the beach on completion of the analysis. If, for any reason, it is not feasible or permissible to take samples to a laboratory, size analysis can be undertaken in the field using portable equipment. If it is undesirable to disturb the sediment surface (e.g. due to the presence of lichens or other vegetation), or if the clasts are of cobble or boulder size, the surface particle size should be estimated using calipers, measuring frame or a size comparator.

For subsequent monitoring, a repeat ground topographic survey should be carried out immediately after any FCERM intervention works are completed and thereafter at intervals of at least 12 months (ideally every 6 months at the end of the winter and summer periods) for a period of at least 5 years. Subsequent monitoring can be undertaken using LIDAR surveys at intervals of 5 years or less (if resources are available). If LIDAR surveys or detailed topographic monitoring surveys cannot be undertaken, a Rapid Geomorphological Assessment (RGA) should be undertaken by a suitably experienced geomorphologist (or engineer with geomorphological training) at

annual intervals (equivalent to the annual inspections undertaken of hard defences).

In addition to the geomorphological assessments, ecological surveys should be undertaken at sensitive sites (e.g. SSSIs and SACs where vegetated shingle is a notified feature). A detailed baseline survey should be undertaken to inform the development of the BMP, and prior to any intervention works being undertaken, with follow-up surveys at specified intervals depending on the nature of the interventions and the ecological sensitivity of the site (perhaps annually for the first few years after a major scheme and then at six yearly intervals coincident with SSSI condition assessments).

Appendix A: Shingle beaches identified in this study

Table A1 Site names and coastal setting.

ID	Localities	First order coastal setting	Second order coastal setting	Third order coastal setting
1	Sudbrook Point	Estuary (Severn Estuary)	Open Shore	
2	West Pill, Rogiet	Estuary (Severn Estuary)	Open Shore	
3	Portland Grounds (Redwick to Goldcliff)	Estuary (Severn Estuary)	Open Shore	
4	Goldcliff Pill	Estuary (Severn Estuary)	Open Shore	
5	Newgout Pill, Wentlooge	Estuary (Severn Estuary)	Open Shore	
6	West Usk Lighthouse, Wentlooge	Estuary (Severn Estuary)	Open Shore	
7	Outfall Lane, Wentlooge	Estuary (Severn Estuary)	Open Shore	
8	Cardiff Flats	Estuary (Severn Estuary)	Open Shore	
9	Penarth to Lavernock Point	Estuary (Severn Estuary)	Open Shore	
10	Lavernock Point to Swanbridge	Inlet (Bristol Channel)	Open Shore	
11	Barry Harbour	Inlet (Bristol Channel)	Bay (Barry Harbour)	
12	Watch House Bay, Barry	Inlet (Bristol Channel)	Bay (Watch House Bay)	
13	Pebble Beach, Barry	Inlet (Bristol Channel)	Open Coast	
14	Porthkerry	Inlet (Bristol Channel)	Open Coast	
15	Bulwarks Fort to Rhoose Point	Inlet (Bristol Channel)	Open Coast	
16	Watch House Beach, East Aberthaw	Inlet (Bristol Channel)	Open Coast	
17	Leys Beach, East Aberthaw	Inlet (Bristol Channel)	Open Coast	
18	West Aberthaw	Inlet (Bristol Channel)	Open Coast	
19	Aberthaw to St Donats	Inlet (Bristol Channel)	Open Coast	
20	Nash Point to Cwm Nash	Inlet (Bristol Channel)	Open Coast	
21	Traeth Mawr, Broughton	Inlet (Bristol Channel)	Open Coast	
22	Traeth Bach, Broughton	Inlet (Bristol Channel)	Open Coast	
23	Dunraven Bay	Inlet (Bristol Channel)	Bay (Dunraven Bay)	
24	Ogmore-by-Sea	Inlet (Bristol Channel)	Open Coast	
25	Pwll y Defaid, Merthyr-mawr Warren	Inlet (Bristol Channel)	Estuary (Ogmore River)	
26	Black Rocks, Porthcawl	Inlet (Bristol Channel)	Open Coast	
27	Trecco Bay, Porthcawl	Inlet (Bristol Channel)	Bay (Trecco Bay)	
28	Seafront Beach, Porthcawl	Inlet (Bristol Channel)	Open Coast	
29	West Beach, Porthcawl	Inlet (Bristol Channel)	Open Coast	
30	Rest Bay, Porthcawl	Inlet (Bristol Channel)	Open Coast	
31	Kenfig Sands	Inlet (Bristol Channel)	Open Coast	
32	Afon Cyffig	Inlet (Bristol Channel)	Open Coast	
33	Margam Sands	Inlet (Bristol Channel)	Open Coast	
34	Port Talbot Harbour	Inlet (Bristol Channel)	Bay (Swansea Bay)	Bay (Port Talbot Harbour)
35	Baglan Burrows	Inlet (Bristol Channel)	Bay (Swansea Bay)	
36	Mumbles	Inlet (Bristol Channel)	Bay (Swansea Bay)	
37	Bracelet Bay, Gower	Inlet (Bristol Channel)	Open Coast	
38	Limeslade Bay, Gower	Inlet (Bristol Channel)	Open Coast	
39	Langland Bay, Gower	Inlet (Bristol Channel)	Bay (Langland Bay)	
40	Caswell Bay	Inlet (Bristol Channel)	Bay (Caswell Bay)	
41	Brandy Cove	Inlet (Bristol Channel)	Open Coast	
42	Pwlldu Bay	Inlet (Bristol Channel)	Bay (Pwlldu Bay)	
43	Pobbles Beach	Inlet (Bristol Channel)	Open Coast	
44	Pennard Burrows	Inlet (Bristol Channel)	Bay (Threecliff Bay)	
45	Oxwich Bay	Inlet (Bristol Channel)	Bay (Oxwich Bay)	
46	Holy's Wash	Inlet (Bristol Channel)	Open Coast	
47	Port-Eynon Bay	Inlet (Bristol Channel)	Bay (Port-Eynon Bay)	
48	Port-Eynon Point	Inlet (Bristol Channel)	Open Coast	
49	Overton Mere	Inlet (Bristol Channel)	Open Coast	
50	Common Cliff	Inlet (Bristol Channel)	Open Coast	
51	Ram Grove	Inlet (Bristol Channel)	Open Coast	
52	Kitchen Corner south	Inlet (Bristol Channel)	Open Coast	
53	Kitchen Corner north	Inlet (Bristol Channel)	Open Coast	
54	Rhossili Bay	Inlet (Bristol Channel)	Bay (Rhossili Bay)	
55	Whiteford Point	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	
56	Machynys, Loughor Estuary	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	Inlet (Burry Inlet)
57	Llanelli Harbour Mouth	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	Inlet (Burry Inlet)
58	Tywyn Bach, Burry Port	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	Inlet (Burry Inlet)
59	Millenium Coastal Park, Burry Port	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	Inlet (Burry Inlet)
60	Burry Port Harbour Mouth	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	Inlet (Burry Inlet)
61	St Ishmael's Scar	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	Estuary (Gwendraeth)
62	The Graig, Ferryside	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	Estuary (River Towy)
63	Ferryside	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	Estuary (River Towy)
64	Ginst Point	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	Estuary (River Towy)
65	Pendine	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	
66	Morfa Bychan, Pendine	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	
67	Marros Sands	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	
68	Amroth Beach	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	
69	Wiseman's Bridge Beach	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	Bay (Saundersfoot Bay)
70	Saundersfoot Beach	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	Bay (Saundersfoot Bay)
71	Rhode Wood, Saundersfoot	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	Bay (Saundersfoot Bay)
72	Monkstone Beach	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	
73	Waterwynch Bay	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	Bay (Waterwynch Bay)
74	Second Bay, Tenby	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	Bay (Second Bay)
75	First Bay, Tenby	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	Bay (First Bay)
76	Tenby South Beach	Inlet (Bristol Channel)	Bay (Carmarthen Bay)	
77	Drinkim Beach, Caldy Island	Inlet (Bristol Channel)	Open Coast	
78	Sandtop Bay, Caldy Island	Inlet (Bristol Channel)	Open Coast	
79	Lydstep Haven	Inlet (Bristol Channel)	Bay (Lydstep Haven)	
80	Church Doors, Skrinkle Haven	Inlet (Bristol Channel)	Open Coast	
81	Manorbier Bay	Inlet (Bristol Channel)	Bay (Manorbier Bay)	

Table A1 (continued)

ID	Localities	First order coastal setting	Second order coastal setting	Third order coastal setting
82	Swanlake Bay	Inlet (Bristol Channel)	Bay (Swanlake Bay)	
83	Privar	Inlet (Bristol Channel)	Bay (Freshwater East)	
84	Greenala Point to Stackpole Quay	Inlet (Bristol Channel)	Open Coast	
85	Stackpole Quay	Inlet (Bristol Channel)	Open Coast	
86	Mowingword	Inlet (Bristol Channel)	Open Coast	
87	Bullslaughter Bay	Open Coast (Celtic Sea)	Open Coast	
88	Flimston Bay	Open Coast (Celtic Sea)	Open Coast	
89	Pen-y-holt Bay	Open Coast (Celtic Sea)	Open Coast	
90	Hobbyhorse Bay	Open Coast (Celtic Sea)	Open Coast	
91	Blucks Pool	Open Coast (Celtic Sea)	Bay (Freshwater West)	
92	Frainslake Sands	Open Coast (Celtic Sea)	Bay (Freshwater West)	
93	Little Furzenip	Open Coast (Celtic Sea)	Bay (Freshwater West)	
94	Freshwater West	Open Coast (Celtic Sea)	Bay (Freshwater West)	
95	Gravel Bay	Open Coast (Celtic Sea)	Bay (Freshwater West)	
96	West Pickard Bay	Open Coast (Celtic Sea)	Open Coast	
97	West Angle Bay	Open Coast (Celtic Sea)	Inlet (Milford Haven)	Bay (West Angle Bay)
98	The Ridge, Angle Bay	Open Coast (Celtic Sea)	Inlet (Milford Haven)	Bay (Angle Bay)
99	Angle Bay East	Open Coast (Celtic Sea)	Inlet (Milford Haven)	Bay (Angle Bay)
100	Pembroke Dock	Open Coast (Celtic Sea)	Inlet (Milford Haven)	Estuary (Pembroke River)
101	Coshaston Point to Mill Bay, Daugleddau	Open Coast (Celtic Sea)	Inlet (Milford Haven)	Estuary (Daugleddau)
102	Burton Ferry	Open Coast (Celtic Sea)	Inlet (Milford Haven)	Estuary (Daugleddau)
103	Neyland	Open Coast (Celtic Sea)	Inlet (Milford Haven)	
104	Llanstadwell	Open Coast (Celtic Sea)	Inlet (Milford Haven)	
105	Newton Noyes, Milford Haven	Open Coast (Celtic Sea)	Inlet (Milford Haven)	
106	Gelliswick Bay, Milford Haven	Open Coast (Celtic Sea)	Inlet (Milford Haven)	Bay (Gelliswick Bay)
107	Gelliswick Village, Milford Haven	Open Coast (Celtic Sea)	Inlet (Milford Haven)	
108	Little Wick, Milford Haven	Open Coast (Celtic Sea)	Inlet (Milford Haven)	
109	Kilroom	Open Coast (Celtic Sea)	Inlet (Milford Haven)	
110	Sandy Haven	Open Coast (Celtic Sea)	Inlet (Milford Haven)	Bay (Sandy Haven)
111	Sleeping Bay	Open Coast (Celtic Sea)	Inlet (Milford Haven)	
112	Butts Bay	Open Coast (Celtic Sea)	Inlet (Milford Haven)	
113	Longoar Bay	Open Coast (Celtic Sea)	Inlet (Milford Haven)	
114	Lindsway Bay	Open Coast (Celtic Sea)	Inlet (Milford Haven)	
115	Wenall Bay	Open Coast (Celtic Sea)	Inlet (Milford Haven)	
116	Watch House Bay, Milford Haven	Open Coast (Celtic Sea)	Inlet (Milford Haven)	
117	Monk Haven	Open Coast (Celtic Sea)	Inlet (Milford Haven)	
118	Musselwick	Open Coast (Celtic Sea)	Inlet (Milford Haven)	Bay (Dale Roads)
119	Pickleridge Beach	Open Coast (Celtic Sea)	Inlet (Milford Haven)	Bay (Dale Roads)
120	Dale Beach	Open Coast (Celtic Sea)	Inlet (Milford Haven)	Bay (Dale Roads)
121	Castlebeach Bay	Open Coast (Celtic Sea)	Inlet (Milford Haven)	
122	Watwick Bay	Open Coast (Celtic Sea)	Inlet (Milford Haven)	
123	Mill Bay	Open Coast (Celtic Sea)	Inlet (Milford Haven)	
124	Windmill Cove	Open Coast (Celtic Sea)	Open Coast	
125	Westdale Bay	Open Coast (Celtic Sea)	Open Coast	
126	Marloes Sands	Open Coast (Celtic Sea)	Bay (Marloes Sands)	
127	Albion Sands	Open Coast (Celtic Sea)	Restricted (Broad Sound)	
128	Watery Bay	Open Coast (Celtic Sea)	Restricted (Broad Sound)	
129	Victoria Bay	Open Coast (Celtic Sea)	Restricted (Broad Sound)	
130	Little Castle Bay	Open Coast (Celtic Sea)	Restricted (Broad Sound)	
131	Rainy Rock Bay	Open Coast (Celtic Sea)	Restricted (Broad Sound)	
132	Three Doors Bay	Open Coast (Celtic Sea)	Restricted (Broad Sound)	
133	Deadman's Bay	Open Coast (Celtic Sea)	Restricted (Broad Sound)	
134	Renny Slip	Open Coast (Celtic Sea)	Restricted (Broad Sound)	
135	Jeffry's Haven south	Open Coast (Celtic Sea)	Restricted (Jack Sound)	
136	Jeffry's Haven north	Open Coast (Celtic Sea)	Restricted (Jack Sound)	
137	Martin's Haven	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
138	West hook Farm	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
139	Mill Haven	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
140	Brandy Bay	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
141	Messelwick	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
142	Rook's Bay	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
143	Little Haven	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
144	The Settlands	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
145	Broad Haven	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
146	Harold Stone south	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
147	Harold Stone north	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
148	Black Point south	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
149	Settling Nose south	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
150	Settling Nose north	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
151	Druidston Haven	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
152	North Haven	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
153	Madoc's Haven	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
154	Nolton Haven	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
155	Newgale Sands: Maidenhall Pt-Bathesland	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
156	Newgale Sands: Bathesland-Sibbernock	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
157	Newgale Sands:Sibbernock-Newgale	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
158	Porthmynawyd	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
159	Aber Dwyrain	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
160	Porth y Bwch, Solva	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
161	Gwadrn, Solva	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
162	Loch Warren	Open Coast (Celtic Sea)	Bay (St Brides Bay)	

Table A1 (continued)

ID	Localities	First order coastal setting	Second order coastal setting	Third order coastal setting
163	Aber Llong	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
164	Porth y Rhaw	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
165	Caer Bwdy Bay	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
166	Caerfai Bay	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
167	Porthlysgi Bay	Open Coast (Celtic Sea)	Bay (St Brides Bay)	
168	Porth Lleuog, Ramsey Island	Open Coast (Celtic Sea)		
169	Aber Mawr, Ramsey Island	Open Coast (Celtic Sea)		
170	Whitesands Bay	Open Coast (Celtic Sea)	Bay (Whitesands Bay)	
171	Porth Lleuog	Open Coast (Celtic Sea)	Bay (Whitesands Bay)	
172	Porthmelgan	Open Coast (Celtic Sea)	Bay (Whitesands Bay)	
173	Porth y Rhaw	Open Coast (Irish Sea/St Georges Channel)		
174	Abereiddi Bay	Open Coast (Irish Sea/St Georges Channel)		
175	Traeth Llyfn	Open Coast (Irish Sea/St Georges Channel)		
176	Porth Egr	Open Coast (Irish Sea/St Georges Channel)		
177	Aberfelin, Trefin	Open Coast (Irish Sea/St Georges Channel)		
178	Pwll Olfa	Open Coast (Irish Sea/St Georges Channel)		
179	Pwll Llong	Open Coast (Irish Sea/St Georges Channel)		
180	Pwll Whiting	Open Coast (Irish Sea/St Georges Channel)		
181	Ynys Deullyn	Open Coast (Irish Sea/St Georges Channel)		
182	Aber Castle	Open Coast (Irish Sea/St Georges Channel)		
183	Pwllstrodur	Open Coast (Irish Sea/St Georges Channel)		
184	Aber Mawr	Open Coast (Irish Sea/St Georges Channel)		
185	Aber Bach, St Nicholas	Open Coast (Irish Sea/St Georges Channel)		
186	Porth Dwgan	Open Coast (Irish Sea/St Georges Channel)		
187	Pwllcrochan	Open Coast (Irish Sea/St Georges Channel)		
188	Pwllawnau	Open Coast (Irish Sea/St Georges Channel)		
189	Pwll Deri	Open Coast (Irish Sea/St Georges Channel)		
190	Porth Maenmelyn	Open Coast (Irish Sea/St Georges Channel)		
191	Pwlluog	Open Coast (Cardigan Bay)		
192	Porthsychan	Open Coast (Cardigan Bay)		
193	Aber Felin	Open Coast (Cardigan Bay)		
194	Porth Maen	Open Coast (Cardigan Bay)		
195	Pwll Hir	Open Coast (Cardigan Bay)	Bay (Fishguard Bay)	
196	Goodwick Sands North	Open Coast (Cardigan Bay)	Bay (Fishguard Bay)	
197	Goodwick Sands South	Open Coast (Cardigan Bay)	Bay (Fishguard Bay)	
198	Lampit Mawr	Open Coast (Cardigan Bay)	Bay (Fishguard Bay)	
199	Aber Gwaun	Open Coast (Cardigan Bay)	Bay (Fishguard Bay)	
200	Pwll Landdu	Open Coast (Cardigan Bay)	Bay (Fishguard Bay)	
201	Pwell Edyn	Open Coast (Cardigan Bay)	Bay (Fishguard Bay)	
202	Pwll Ceunant	Open Coast (Cardigan Bay)	Bay (Fishguard Bay)	
203	Aber Richard	Open Coast (Cardigan Bay)	Bay (Fishguard Bay)	
204	Pwll y Blewyn	Open Coast (Cardigan Bay)	Bay (Fishguard Bay)	
205	Aber Grugog	Open Coast (Cardigan Bay)	Bay (Fishguard Bay)	
206	Aber Hywel	Open Coast (Cardigan Bay)	Bay (Fishguard Bay)	
207	Carreg Pen-las	Open Coast (Cardigan Bay)	Bay (Fishguard Bay)	
208	Aber Bach, Fishguard	Open Coast (Cardigan Bay)	Bay (Fishguard Bay)	
209	Pwll Gwylog	Open Coast (Cardigan Bay)	Bay (Fishguard Bay)	
210	Cwm-yr-Eglwys, Afon Teifi	Open Coast (Cardigan Bay)	Bay (Newport Bay)	
211	Aber Fforest	Open Coast (Cardigan Bay)	Bay (Newport Bay)	
212	Aber Rhigian	Open Coast (Cardigan Bay)	Bay (Newport Bay)	
213	Traeth Cell-Howel	Open Coast (Cardigan Bay)		
214	Ceibwr Bay	Open Coast (Cardigan Bay)		
215	Traeth y Rhedyn	Open Coast (Cardigan Bay)		
216	Traeth Godir-coch	Open Coast (Cardigan Bay)		
217	Careg Aderyn	Open Coast (Cardigan Bay)	Bay (Afon Teifi estuary)	
218	Pwll Edrych	Open Coast (Cardigan Bay)	Bay (Afon Teifi estuary)	
219	Pwll Melyn	Open Coast (Cardigan Bay)	Bay (Afon Teifi estuary)	
220	Pen yr Ergyd	Open Coast (Cardigan Bay)	Esuary (Afon Teifi)	
221	Llangrannog	Open Coast (Cardigan Bay)		
222	Traeth y Gaerlwyd	Open Coast (Cardigan Bay)		
223	Cwmtydu	Open Coast (Cardigan Bay)		
224	Castell Bach	Open Coast (Cardigan Bay)		
225	Traeth y Coubal	Open Coast (Cardigan Bay)		
226	Llech Cimwch	Open Coast (Cardigan Bay)		
227	Traeth y Quarry	Open Coast (Cardigan Bay)		
228	New Quay Bay	Open Coast (Cardigan Bay)	Bay (New Quay Bay)	
229	Little Quay Bay	Open Coast (Cardigan Bay)	Bay (Little Quay Bay)	
230	Gilfach-yr-Halen to Clogfryn	Open Coast (Cardigan Bay)		
231	Aberaeron south	Open Coast (Cardigan Bay)		
232	Aberaeron north	Open Coast (Cardigan Bay)		
233	Aberaeron to Aberarth	Open Coast (Cardigan Bay)		
234	Aberarth	Open Coast (Cardigan Bay)		
235	Aberarth to Morfa Mawr	Open Coast (Cardigan Bay)		
236	Morfa Mawr	Open Coast (Cardigan Bay)		
237	Morfa Mawr to Llanonn	Open Coast (Cardigan Bay)		
238	Llanonn	Open Coast (Cardigan Bay)		
239	Llanonn to Llansantffraid	Open Coast (Cardigan Bay)		
240	Llansantffraid	Open Coast (Cardigan Bay)		
241	Llansantffraid to Llanrhystud	Open Coast (Cardigan Bay)		
242	Llanrhystud	Open Coast (Cardigan Bay)		
243	Llanrhystud to Carreg Ti-pw	Open Coast (Cardigan Bay)		

Table A1 (continued)

ID	Localities	First order coastal setting	Second order coastal setting	Third order coastal setting
244	Carreg Ti-pw to Pinderi Cliffs	Open Coast (Cardigan Bay)		
245	Twl Twrw to Traeth Tanybwloch	Open Coast (Cardigan Bay)		
246	Traeth Tanybwloch, Aberystwyth	Open Coast (Cardigan Bay)		
247	South Beach, Aberystwyth	Open Coast (Cardigan Bay)		
248	North Beach, Aberystwyth	Open Coast (Cardigan Bay)
